PLEASE NOTE -
This version of the EMC 2024 Abstract Book is without any graphics

Table of Content

11 Digital Holographic Microscopy of Pseudomonas aeruginosa to Probe Effects of Membrane Active Antimicrobials
Mrs Elizabeth Ison[1,2], Dr Robert P Howlin[3], Dr Ricarda O Hawkins[3], Dr David J Bradshaw[3], Prof Paul Williams[2], Prof Morgan R Alexander[1]
[1]School of Pharmacy, University of Nottingham, Nottingham, United Kingdom, [2]BioDiscovery Institute, University of Nottingham, Nottingham, United Kingdom, [3]Haleon, Weybridge, United Kingdom
12 Single Crystal Analysis of Nanocrystals by Three-Dimensional Electron Diffraction
Dr. Zhehao Huang[1]
[1]Stockholm University, Stockholm, Sweden
13 Enhancing Nanomechanical Properties of MXene through Tailored Surface Potential: PFQNM and Kelvin Force Microscopy Studies
Jing Li[1]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden
14 Elimination of Human Error during CPD Process in Plant Tissue Preparation for Electron Microscopy.
Anna Walkiewicz[1]
[1]Quorum Technologies, Laughton, United Kingdom
16 SEM-micro-photogrammetry and stereo reconstruction
on the Tescan Amber X electron microscope

Evgenii Modin[1], Andrey Chuvilin
[1]CIC NanoGune BRTA, San Sebastian, Spain
17 Development state of the CEOS ground-potential monochromator
Felix Börrnert[1], Stephan Uhlemann[1], Heiko Müller[1], Volker Gerheim[1], Klaus Hessenauer[1], Holger Schulz[1], Maximilian Haider[1]
[1]CEOS GmbH, Heidelberg, Germany
18 Miniaturized material testing devices for multimodal in situ microscopic studies
Matthias Weber[1], Dr. Julian Müller[1], Dr. Rainer Steinheimer[2], Prof. Robert Brandt[3], Prof. Axel von Hehl[4], Prof. Benjamin Butz[1]
[1]Micro- and Nanoanalytics Group, University of Siegen, Siegen, Germany, [2]Lehrstuhl für Umformtechnik, University of Siegen, Siegen, Germany, [3]Lehrstuhl für Werkstoffsysteme für den Fahrzeugleichtbau, University of Siegen, Siegen, Germany, [4]Lehrstuhl für Materialkunde und Werkstoffprüfung, University of Siegen, Siegen, Germany
19 Using the YOLO DeepLearning algorithm to quantify the rAAV empty/filled ratio from Cryo-EM imaging
Manon Mirgaux[1], William Amadou[1], Louise Conrard[1], Egor Zindy[1], Ayse Betul Oktay[1], Professor David Perez-Morga[1], Professor Olivier Debeir[1]
[1]Université Libre de Bruxelles, Gosselies, Belgium
20 The behavior of additive manufactured aluminum alloys upon anodization
Lydia Daum[1], Dr. Stefan Ostendorp[1], Dr. Martin Peterlechner[2], Prof. Dr. Gerhard Wilde[1]
[1]Institute of Materials Physics, University of Münster, Münster, Germany, [2]Laboratory of Electron Microscopy, Karlsruhe Institute of Technology, Karlsruhe, Germany
21 Local mobility and atomic structure in Pd- and Zr-based bulk metallic glasses
Olivia Vaerst[1], Dr Harald Rösner[1], Dr Martin Peterlechner[2], Prof Dr Gerhard Wilde[1]
[1]University of Münster, Institute of Materials Physics, Münster, Germany, [2]Karlsruhe Institute of Technology, Laboratory for Electron Microscopy , Karlsruhe, Germany
22 Seeing the nanoscale dynamics in gas-based processes by using in-situ TEM

Tanmay Ghosh[1,3], Ms Tjiu Weng Weei[1], Mr. Khakimjon Saidov[2,3], Mr. Antoine Pacco[5], Mr Harold Philipsen[5], Mr Utkur Mirsaidov[2,3,4], Mr Zainul Aabdin[1]
[1]Institute of Materials Research and Engineering, A*STAR (Agency for Science, Technology, and Research), Singapore 138634, Singapore, Singapore, [2]Center for Advanced 2D Materials and Department of Physics, National University of Singapore, Singapore 117546, Singapore, Singapore, [3]Center for BioImaging Sciences and Department of Biological Sciences, National University of Singapore, Singapore 117557, Singapore, Singapore, [4]Department of Materials Science and Engineering, National University of Singapore, Singapore 117575, Singapore, Singapore, [5]imec, Kapeldreef 75, Leuven, B-3001, Belgium, Leuven, Belgium

23 Single particle CryoEM structures using iDPC-STEM from 4D-STEM detectors at near-atomic resolution

Daniel Mann[1], Aikaterini Filopoulou[1], Max Leo Leidl[1,4], Mr Maarten Wirix[2], Mr Ivan Lazic[2], Knut Mueller-Caspary[4], Mr. Carsten Sachse[1,3]
[1]Ernst Ruska Centre 3, Forschungszentrum Juelich, Juelich, Germany, [2]Thermo Fisher Scientific, Eindhoven, Netherlands, [3]Heinrich Heine University, Duesseldorf, Germany, [4]Ludwig Maximilian University, Munich, Germany

24 The Best of Both Worlds: Combining Label Free and Fluorescence Imaging with Livecyte

Peter Djali[1], Dr Meetal Jotangia[1]
[1]Phase Focus Ltd, Sheffield, United Kingdom

25 The Electron Bio-Imaging Centre (eBIC) at Diamond Light Source, UK

Lorna Malone[1], Dr Eilis Bragginton[1]
[1]eBIC, Diamond Light Source, Oxford, United Kingdom

26 XRD and TEM study of the quasicrystalline phase in pellets consolidated using spark plasma sintering

Dr Ruitao Li[1,2], Dr Khiam Aik Khor[3], Dr Zaoli Zhang[4], Dr Chris B Boothroyd[2], Associate Professor Zhili Dong[2]
[1]School of Mechanical Engineering, Jiangsu University, Zhenjiang, China, [2]School of Materials Science and Engineering, Nanyang Technological University, Singapore, Singapore, [3]School of Mechanical & Aerospace Engineering, Nanyang Technological University, Singapore, Singapore, [4]Erich Schmid Institute of Materials Science Austrian Academy of Sciences, Leoben, Austria

27 In vitro genotoxic activity of leaf and flower extracts of four alien invasive plant species

Mirela Uzelac Bozac[1], Dr Petra Cvjetko[2], Dr Katarina Caput Mihalić[2], Miss Ela Kukac[3], Dr Slavica Dudaš[4], Dr Barbara Sladonja[1], Dr Danijela Poljuha[1]
[1]Institute of Agriculture and Tourism, Porec, Croatia, [2]Faculty of Science, University of Zagreb, Zagreb, Croatia, [3]Department of Biotechnology, University of Rijeka, Rijeka, Croatia, [4]Agricultural Department, Polytechnic of Rijeka, Rijeka, Croatia

28 Examination of the Thermal and Morphological properties of Spartium Junceum Fibers for Flame Retardant Purposes

Zorana Kovacevic[1], Mrs. Lucia Spasevski[2], Prof.Dr. SANDRA BISCHOF[1]
[1]University of Zagreb Faculty of Textile Technology, Zagreb, Croatia, [2]Oxford Instruments NanoAnalysis, High Wycombe, United Kingdom

29 Momentum-resolved EELS and CL investigation on 1D-plasmonic crystal fabricated by focused ion beam method

Dr. Akira Yasuhara[1], Masateru Shibata[1], Wakaba Yamamoto[1], Izzah Machfuudzoh[2], Sotatsu Yanagimoto[2], Takumi Sannomiya[2]
[1]JEOL Ltd., Akishima, Japan, [2]Tokyo Institute of Technology, Yokohama, Japan

30 Analyses of Observed Speciation of Cobalt in NMC cathodes Using Laboratory X-ray Absorption Spectroscopy (XAS)

Andreas Bergner[1], Simon John[1]
[1]Quantum Design GmbH, Pfungstadt, Germany

31 Observing Lithium Ion Battery Bonds During Charge Cycling Using Laboratory XAS

Andreas Bergner[1], Simon John[1]
[1]Quantum Design GmbH, Pfungstadt, Germany

32 In situ microscopic observations of zinc electrodeposition process in various electrolytes

Dr Kaname Yoshida[1], Dr. Yuki Sasaki[1], Dr. Akihide Kuwabara[1], Prof. Yuichi Ikuhara[1,2]
[1]Japan Fine Ceramics Center, Nagoya, Japan, [2]The University of Tokyo, Bunkyo-ku, Japan

33 Enabling discovery with in-cell Cryo-ET & AlphaFold: Identification of a non-canonical translocation complex

Rasmus Kjeldsen Jensen[1], Liang Xue[1], Federico Marotta[1], Joseph Chris Somody[1], Joel Selkrig[2], Swantje Lenz[3], Nassos Typas[2], Maria Zimmermann-Kogadeeva[2], Juri Rappsilber[3], Peer Bork[1], Julia Mahamid[1]
[1]Structural and Computational Biology, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, [2]Genome Biology unit, EMBL, Heidelberg, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, [3]Bioanalytics Unit, Institute of Biotechnology, Technische Universität, Berlin, Germany

34 Chemical and structural investigations of epitaxial Fe-Cr-O thin films

Dr Benedicte Warot-Fonrose[1], Dr Pamella Vasconcelos Borges Pinho[2], Dr Alain Chartier[2], Dr Antoine Barbier[3], Dr Denis Menut[4], Dr Myrtille Hunault[4], Dr Cecile Marcelot[1], Dr Frederic Miserque[2], Dr Jean-Baptiste Moussy[3]
[1]CEMES-CNRS, Toulouse, France, [2]Université Paris-Saclay, CEA, Service de recherche en Corrosion et Comportement des Matériaux, Saclay, France, [3]Université Paris-Saclay, CEA, CNRS, SPEC, Saclay, France, [4]Synchrotron SOLEIL, Gif sur Yvette, France

35 Electron and x-ray spectroscopy for real-space electronic structure mapping in superconducting nickelates

Berit Goodge[1]
[1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

36 An advanced smart counting mode for pixelated direct electron detectors based on semiconductors

Dr. Björn Eckert[1], Mr. Stefan Aschauer[1], Mr. Martin Huth[1], Mrs. Petra Majewski[1], Mrs. Heike Soltau[1], Mr. Lothar Strüder[2]
[1]PNDetector, München, Germany, [2]PNSensor, München, Germany, [3]University of Siegen, Siegen, Germany

37 Manipulating topological magnetic structures by in-situ Lorentz microscopy

Dongsheng Song[1]
[1]Institutes of Physical Science and Information Technology, Anhui University, Hefei 230601, China, Hefei, China

38 HeXI: The High-energy Electron Xtallography Instrument at Diamond Light Source

Pedro Nunes[1], Mark Lunnon[1], Bodvar Olafsson[1], Andrew Foster[1], Richard Littlewood[1], Graham Duller[1], Gwyndaf Evans[1,2], Alistair Siebert[1]
[1]Diamond Light Source, Harwell, United Kingdom, [2]The Rosalind Franklin Institute, Harwell, United Kingdom

39 Understanding strain and composition effects in fuel cell catalysts using advanced electron microscopy and DFT

Alessandro Zanre[1], Dr. Aaakash Varambhia[2], Dr. Dogan Ozkaya[2], Dr. Xiaonan Luo[3], Prof. Sergio Lozano-Perez[1], Prof. Rebecca J. Nicholls[1], Prof. Peter D. Nellist[1]

[1]Department of Materials, University of Oxford, , United Kingdom, [2]Johnson Matthey Technology Centre, , United Kingdom, [3]Contemporary Amperex Technology Co., Limited, , P. R. China

40 Array tomography enables correlative volume electron microscopy and spatial transcriptomics

Mr Georg Kislinger[1,7], Mr Peter Androvic[2], Mr Gunar Fabig[5], Mr Igor Khalin[2], Mr Nikolaus Plesnila[2], Mr Thomas Misgeld[1,3,7], Mr Thomas Müller-Reichert[5], Mr Oz Gokce[2,5], Martina Schifferer[1,3]
[1]German Center for Neurodegenerative Diseases, Munich, Germany, [2]University Hospital of Munich, LMU, Munich, Germany, [3]Munich Cluster of Systems Neurology (SyNergy), Munich, Germany, [4]University Hospital Bonn, Bonn, Germany, [5]Technische Universität Dresden, Dresden, Germany, [6]Institute for Stroke and Dementia Research, LMU, Munich, Germany, [7]Technical University Munich, Munich, Germany

41 Thermoelectric structure-property relationship establishment in TlGaSe2

Mr Tigran Simonian[1,2], Dr. Ahin Roy[1,2], Dr. Akash Bajaj[3], Dr. Rui Dong[3], Prof. Zdenek Sofer[4], Prof. Stefano Sanvito[3], Prof. Valeria Nicolosi[1,2]
[1]Advanced Microscopy Lab, Trinity College Dublin, Dublin, Ireland, [2]School of Chemistry, Trinity College Dublin, Dublin, Ireland, [3]School of Physics, Trinity College Dublin, Dublin, Ireland, [4]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Prague, Czech Republic

42 Nanoparticle size estimation by HR-STEM and generative AI

Henrik Eliasson[1], Mr. Angus Lothian[2], Mr Ivan Surin[3], Dr. Sharon Mitchell[3], Professor Javier Pérez-Ramírez[3], Professor Rolf Erni[1]
[1]Electron Microscopy Center, Empa – Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland, [2]Computer Vision Laboratory, Department of Electrical Engineering, Linköping University, Linköping, Sweden, [3]Department of Chemistry and Applied Biosciences, ETH Zürich, Zürich, Switzerland

43 Nanoscale phase separation in novel Zr-based metallic glasses

Devinder Singh[1,2], Dr. Anna Sophie Jelinek[3], Dr. Parthiban Ramasamy[1], Dr. Rahul Bhattacharya[1], Dr. Zhuo Chen[1], Mr. Simon Fellner[1], Dr. Christoph Gammer[1], Dr. Zaoli Zhang[1], Prof. Jürgen Eckert[1,3]
[1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Leoben, Austria, [2]Amity School of Applied Sciences, Amity University, Lucknow, India, [3]Department of Materials Science, Montanuniversität Leoben, Leoben, Austria

44 TRIBLOCK POLY(2-OXAZOLINE)S WITH A FLUORINATED BLOCK AS A NEW PLATFORM FOR ADVANCED SELF-ASSEMBLY: CRYO-TEM STUDY

Sergey Filippov[1], Dr. Leonid Kaberov[2], Dr. Lubomir Kovacik[3], Prof. Richard Hoogenboom[4]
[1]DWI Institute of Interactive Materials, Aachen, Germany, [2]Friedrich Schiller University, Jena, Germany, [3]C-CINA, Biozentrum, University of Basel, Basel, Switzerland, [4]Ghent University, Ghent, Belgium

45 Tunneling nanotubes provide a route for SARS-CoV-2 spreading

Anna Pepe[1], Mr Stefano Pietropaoli[2], Mr Matthijn Vos[3], Mrs Giovanna Barba-Spaeth[4], Mrs Chiara Zurzolo[5]
[1]Unité de Trafic Membranaire et Pathogénèse, Département de Biologie Cellulaire et Infection, Institut Pasteur, CNRS UMR3691, Université Paris Cité., Paris, , [2]Catalent Pharma Solutions, Frosinone, , [3]Plateforme Technologique Nanoimagerie Institut Pasteur, Paris, , [4]Unité de Virologie Structurale, CNRS UMR 3569 Département de Virologie, Institut Pasteur, Paris, , [5]Unité de Trafic Membranaire et Pathogénèse, Département de Biologie Cellulaire et Infection, Institut Pasteur, Paris,

46 Interdiffusion-controlled phase formation at an interconnect interface during soldering

Sandra Gaertner[1], Dr. Harald Rösner[1], Apl. Prof Dr. Sergiy Divinskiy[1], Prof. Dr. Gerhard Wilde[1]
[1]Institute of Materials Physics, University Münster, Münster, Germany

47 Machine Learning Algorithms for Tracking Analysis

of Chloroplast Avoidance Movements

MSc Aleksander Luboński[1], Mr. Sławomir Samardakiewicz[1]
[1]Laboratory of Electron and Confocal Microscopy, Faculty of Biology, Adam Mickiewicz University, Poznań, Poland

48 (In-situ) 3DED and other TEM Techniques Unravel (Ca,Sr)(Mn,Fe)O3-δ and LaxSr2-xMnO4-δ Structure-Property Relations in Redox Conditions

Daphne Vandemeulebroucke[1], Dr. Maria Batuk[1], Mr. Amirhossein Hajizadeh[1], Dr. Pascal Roussel[2], Dr. Myriam Wastiaux[2], Prof. Dr. Joke Hadermann[1]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]UCCS, CNRS, University of Lille, Lille, France

49 In Situ TEM Biasing and Heating of Neuromorphic Gold Nanogranular Nanofilms Showing Resistive Switching

Prof. Andrea Falqui[1], Mr. Alberto Casu[1], Mr. Paolo Milani[1], Ms. Angelica Chiodoni[2], Mr. Yurii Ivanov[3], Mr. Giorgio Divitini[3]
[1]University of Milan, Department of Physics, Milan, Italy, [2]Center for Sustainable Future Technologies @PoliTo, Istituto Italiano di Tecnologia, Turin, Italy, [3]Electron Spectroscopy and Nanoscopy, Istituto Italiano di Tecnologia, Genoa, Italy

50 Electron holography for electrostatic potential measurement and contrast enhanced imaging of biological samples

Dr Elio Karim[1,2,4], Mr. Bumsu Park[1], Mr. Christophe Gatel[1], Ms. Amélie Le Forestier[3], Ms. Vanessa Soldan[2], Ms. Stéphanie Balor[2], Ms. Célia Plisson-Chastang[2], Mr. Pierre-Emmanuel Gleizes[2], Mr. Etienne Snoeck[1]
[1] Centre d'élaboration de matériaux et d'études structurales (CEMES) - CNRS, Toulouse, France, [2]MCD and METi, Centre de Biologie Intégrative, Université de Toulouse, CNRS, Toulouse, France, [3] Laboratoire Physique des Solides (LPS) - Université Paris-Saclay, CNRS, Orsay, France, [4]Institut de Biologie Structurale (IBS) – University Grenoble Alpes, CEA, CNRS, Grenoble, France

51 Investigating the potential variation of in-operando semiconductor nanostructures in electron beam direction

Hüseyin Çelik[1], Mr. Robert Fuchs[2], Dr. Dirk Berger[3], Dr. Christian M. Günther[3], Mr. Simon Gaebel[4], Dr. Tolga Wagner[5], Prof. Dr. Michael Lehmann[1]
[1]Technische Universität Berlin, Institute of Optics and Atomic Physics, , Germany, [2]Technische Universität Berlin, Institute of Theoretical Physics, , Germany, [3]Technische Universität Berlin, Center for Electron Microscopy (ZELMI), , Germany, [4]Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie, , Germany, [5]Humboldt-Universität zu Berlin, Department of Physics, , Germany

52 Differential Phase Contrast Microscopy and Atom Probe Tomography of Ferromagnetism in High-Entropy Alloys

Ms. Shabnam Taheriniya[1], Dr Harald Rösner[1], Mr. Gerhard Wilde[1]
[1]Institute of Materials Physics, University of Münster, 48149 Münster, Germany

53 Optimizing micrograph contrast in multicomponent systems at low-voltage scanning electron microscopy

Asia Matatyaho Ya'akobi[1], Irina Davidovich[1], Yeshayahu Talmon[1]
[1]The Department of Chemical Engineering and The Russell Berrie Nanotechnology Institute (RBNI), Haifa , Israel

54 Vibration-Corrected Electron Ptychography

Anton Gladyshev[1,2], Mr. Johannes Müller[1,2], Dr. Benedikt Haas[1,2], Prof. PhD Christoph Koch1[1,2]
[1]Humboldt-Universität zu Berlin, Berlin, Germany, [2]Center for the Science of Materials Berlin, Berlin, Germany

55 Using Virtual Detectors as a Compression Tool for Electron Ptychography
Anton Gladyshev[1,2], Mr. Marcel Schloz[1,2], Mr. Johannes Müller[1,2], Dr. Benedikt Haas[1,2], Prof. PhD Christoph Koch[1,2]
[1]Humboldt-Universität zu Berlin , Berlin, Germany, [2]Center for the Science of Materials Berlin, Berlin, Germany
56 Advanced Brillouin fibre probes for in situ Brillouin imaging
Irina Kabakova[1]
[1]School of Mathematical and Physical Sciences, University of Technology Sydney , Sydney , Australia
57 DQE measurement for TEM detectors: from the key parameter to an ambiguous estimate
Olivier Marcelot[1], Mme Cecile Marcelot[2]
[1]ISAE-SUPAERO, Toulouse, France, [2]CEMES-CNRS, Toulouse, France
58 Fractal: An open-source framework for reproducible bioimage analysis at scale using OME-Zarrs
Dr. Joel Lüthi[1]
[1]BioVisionCenter, University of Zurich, Zurich, Switzerland
59 Light sheet imaging across scales for preclinical drug discovery research
Yasir Gallero Salas[1], Mr. Max Hahn[1], Mr. Thomas Topilko[1], Ms. Marie Biviano Rosenkilde[1], Ms. Frederikke Lynge Sørensen[1], Ms. Lea Lydolph Larsen[1], Ms. Katrine Skovgård[1], Mr. Urmas Roostalu[1]
[1]Gubra, Hørsholm, Denmark
60 Unlocking Macroscale Solutions with Nanoscale Information:
Towards Next-generation Optoelectronics
Prof Elke Debroye[1], Mr. Handong Jin[1], Mr. Amitrajit Mukherjee[1], Mr. Sudipta Seth[1], Mr. Johan Hofkens[1]
[1]KU Leuven, Department of Chemistry, Leuven, Belgium
61 Comprehensive 3D Characterization Workflow for Solid Oxide Cells
Dr Bartlomiej Winiarski[1], Patrick Barthelemy[2], Chengge Jiao[3], Dirk Laeveren[3], Dalton Cox[4], SA Barnett[4]
[1]Thermo Fisher Scientific, Brno, Czech Republic, [2]Thermo Fisher Scientific, Waltham, USA, [3]Thermo Fisher Scientific, Eindhoven, The Netherlands, [4]Northwestern University, Evanston, USA
62 Optimized Bright Field STEM Imaging for Detecting Molecules absorbed within Zeolite Pores
Yu Xia[1], Mr. Tom WIllhammar[1]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden
63 A Better Insight Into Battery Materials Using A Correlative Approach
Dr Dan Haspel[1], Dr Joshua Lea[1], Dr Jonathan Moffat[1], Dr Pedro Machado[1], Dr James Sagar[1], Dr Louise Hughes[1]
[1]Oxford Instruments, High Wycombe, United Kingdom
65 Quantification of Lithium in State-of-the-Art low Voltage STEM
Pr. Raynald Gauvin[1], Mr. Nicolas Brodusch[1], Mrs. Stéphanie Bessette[1]
[1]Mining and Materials Engineering,McGill University, Montréal, Canada
66 Quantification and Control of Mass Transport in different Liquid-Phase Transmission Electron Microscopy Flow Scenarios
Stefan Merkens[1], Giuseppe De Salvo[1], Christopher Tollan[1], Katarzyna Bejtka[2,3], Marco Fontana[2,3], Angelica Chiodoni[2], Marek Grzelczak[4,5], Andrey Chuvilin[1,6]
[1]CIC nanoGUNE BRTA, Donostia-San Sebastian, Spain, [2]Center for Sustainable Future Technologies@Polito, Istituto Italiano di Tecnologia, Torino, Italy, [3]Department of Applied Science and Technology, Politecnico di Torino, Torino, Italy, [4]Donostia International Physics Center (DIPC), Donostia-San Sebastian, Spain, [5]Centro de Física de Materiales CSIC-UPV/EHU, Donostia-San Sebastian, Spain, [6]Ikerbasque, Bilbao, Spain
67 CoCID: Compact Cell Imaging Device for Correlative Investigation of Hepatitis E Infection

Dr. Christopher Evans[1], Dr. Kenneth Fahy[2], Dr. Sergey Kapishnikov[2,3], Mrs. Tiina O'neill[4], Dr. Dimitri Scholz[4], Ass. Prof. Nicola Fletcher[1,4]
[1]Veterinary Sciences, University College Dublin, , Ireland, [2]SiriusXT, , Ireland, [3]School of Biology and Environmental Science, Univeristy College Dublin, , Ireland, [4]Conway Institute, University College Dublin, , Ireland

68 Picometer-accurate Mapping of Lattice Displacements from Unconventional Room-Temperature Bond Order in Metallic NaRu2O4

Anna Scheid[1], Dr. Arvind Kumar Yogi[1,2], Mrs. Isha[1,2], Dr. Masahiko Isobe[1], Mrs. Birgit Bussmann[1], Dr. Tobias Heil[1], Prof. Dr. Peter A. van Aken[1]
[1]Max Planck Institute for Solid State Research, Stuttgart, Germany, [2]UGC DAE Consortium for Scientific Research, Indore, India

69 Novel Insights into Atomic-Scale Interface Reconstruction during Epitaxial Growth of Metallic Delafossite Thin Films

Anna Scheid[1], Dr. Qi Song[2], Mr. Hari Pokhrel[3], Dr. Tobias Heil[1], Dr. Stephanie Ribet[4], Dr. Colin Ophus[4], Mr. Niklas Enderlein[3], Dr. Y.Eren Suyolcu[1], Prof. Dr. Philipp Hansmann[3], Prof. Dr. Darrell Schlom[2,5,6], Prof. Dr. Peter A. van Aken[1]
[1]Max Planck Institute for Solid State Research, Stuttgart, Deutschland, [2]Department of Materials Sciences and Engineering, Ithaca, USA, [3]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany, [4]National Center for Electron Microscopy, Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, USA, [5]Kavli Institute at Cornell for Nanoscale Science, Ithaca, USA, [6]Leibniz-Institut für Kristallzüchtung, Berlin, Germany

70 FFT denoising methodology through CNN for the study of WS2 vacancies

Ivan Pinto[1], Mr. Marc Botifoll[1], Mr. Yuki Wang[3], Pf. Chen Wang[3], Pf. Jordi Arbiol[1,2]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Barcelona, Spain, [2]ICREA, Pg. Lluis Companys 23, Barcelona, Spain, [3]MSE, Tsinghua University, Beijing, China

71 FFT denoising methodology through CNN for the study of WS2 vacancies

Ivan Pinto[1], Mr. Marc Botifoll[1], Mr. Yuki Wang[3], Pf. Chen Wang[3], Pf. Jordi Arbiol[1,2]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Barcelona, Spain, [2]ICREA, Pg. Lluis Companys 23, Barcelona, Spain, [3]MSE, Tsinghua University, Beijing, China

72 In situ plasma studies using a direct current microplasma in a scanning electron microscope

Robin De Meyer[1,2], Dr. Lukas Grünewald[1], Dr. Dmitry Chezganov[1], Dr. Andrey Orekhov[1], Prof. Sandra Van Aert[1], Prof. Annemie Bogaerts[2], Prof. Sara Bals[1], Prof. Jo Verbeeck[1]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]PLASMANT, University of Antwerp, Antwerp, Belgium

73 Localization techniques in biomedical electron microscopy: good as gold

Wiebke Möbius[1]
[1]Max-Planck-Institute for Multidisciplinary Sciences, Göttingen, Germany

74 Alternating-probe electron ptychography

Meng Zhao[1], Mr. Anton Gladyshev[1], Prof. Christoph Koch[1]
[1]Humboldt University of Berlin & Center for the Science of Materials Berlin,, Berlin, Germany

75 The effect of fragrance molecules on surfactant self-aggregation in aqueous solutions studied by cryo-TEM

Sapir Lifshiz-Simon[1], Prof. Yeshayahu Talmon[1]
[1]Department of Chemical Engineering and the Russell Berrie Nanotechnology Institute (RBNI), Technion – Israel Institute of Technology, Haifa, Israel

76 In-Situ TEM assessment of phase transformation in VO2-based thin films with Ho addition

Ellen Suhr[1], Dr. Aleksander Kostka[2], Prof. Dr.-Ing. Alfred Ludwig[1]

[1]Institute for Materials, Ruhr University Bochum (RUB), , Bochum, Germany, [2]ZGH, Ruhr University Bochum (RUB), , Bochum, Germany

77 SEMNet: Deep Synthetic Training for Unprecedented SEM Image Denoising and Super-Resolution

Junghun Cha[1], Ph.D Doohyun Cho[1], Ph.D SeungJae Lee[1]
[1]D.notitia Inc., Seoul, Republic of Korea

78 Deep learning 3D-mineral liberation analysis with micro-X-ray fluorescence, micro-computed tomography, and deep learning segmentation

Dr. Patrick Tung[1,2], Amalia Halim[1], Dr. Helen Wang[1], Dr. Anne Rich[1], Dr. Xiao Chen[3], Prof. Klaus Regenauer-Lieb[4], Dr. Christopher Marjo[1]
[1]Mark Wainwright Analytical Centre (MWAC), University of New South Wales, UNSW Sydney, Australia, [2]Research Technology Services, University of New South Wales, UNSW Sydney, Australia, [3]Mineral Resources, Commonwealth Scientific and Industrial Research Organisation (CSIRO), Kensington, Australia, [4]WA School of Mines: Minerals, Energy and Chemical Engineering, Australian Resources Research Centre (ARRC), Curtin University, Kensington, Australia

79 Solving the controversy of the metal-insulator phase transition in chromium nitride thin films

Magnus Garbrecht[1], Ms Ashalatha Indiradevi Kamalasanan Pillai[1], Mr Bidesh Biswas[2], Mr Bivas Saha[2]
[1]The University of Sydney, Sydney, Australia, [2]Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, India

80 Ptychographic X-ray computed tomography of porous membranes with nanoscale resolution

Dr. Radoslaw Gorecki[1,2], Carla C. Polo[3], Tiago A. Kalile[3], Eduardo X. S. Miqueles[3], Yuri R. Tonin[3], Lakshmeesha Upadhyaya[1,2], Florian Meneau[3,4], Suzana P. Nunes[1,2,5]
[1]Environmental Science and Engineering Program, Biological and Environmental Science and Engineering, King Abdullah University of Science and Technology (KAUST), KAUST, Thuwal, Saudi Arabia, [2]Advanced Membranes and Porous Materials Center, King Abdullah University of Science and Technology (KAUST), KAUST, Thuwal, Saudi Arabia, [3]Brazilian Synchrotron Light Laboratory (LNLS), Brazilian Center for Research in Energy and Materials (CNPEM), Campinas, Brazil, [4]Institute of Chemistry, University of Campinas (UNICAMP), Campinas, Brazil, [5]Chemistry and Chemical Engineering Programs, Physical Science and Engineering, King Abdullah University of Science and Technology (KAUST), KAUST, Thuwal, Saudi Arabia

81 How Euro-BioImaging can support your research with access to the best imaging tools

Johanna Bischof[1]
[1]Euro-BioImaging ERIC, Heidelberg, Germany

82 Optimizing FIB-based sample preparation for quantitative in-situ biasing studies of semiconductors using 4D-STEM

Vitalii Lider[1], Franziska Hüppe[1], Saleh Firoozabadi[1], Shamail Ahmed[1], Jürgen Belz[1], Andreas Beyer[1], Kerstin Volz[1]
[1]Materials Science Centre and Department of Physics, Philipps University Marburg, Marburg, Germany

83 Inversion of the Internal Electric Field in GaN/AlN Heterostructures Studied by Off-Axis Electron Holography

Lou Denaix[1], Dr Florian Castioni[1], Dr Matthew Bryan[1], Dr David Cooper[1], Dr Eva Monroy[2]
[1]Univ. Grenoble Alpes, CEA, Leti, Grenoble, France, [2]Univ. Grenoble Alpes, CEA, Grenoble INP, Irig, Pheliqs, Grenoble, France

84 Multi-modal correlative microscopy: simultaneous and colocalised Raman & SEM imaging

Dr Jorge Diniz[1], Miss Jennifer Ferguson[1], Mr Pete Johnson[1], Mr Tim Smith[1]
[1]Renishaw plc, New Mills, Wotton-under-Edge, UK

85 Near-Ideal Direct-Electron Focused-Probe 4D-STEM Data for Open-Source Phase Reconstructions

Prof. Toma Susi[1], Niklas Dellby[2], Russ Hayner[2], Christoph Hofer[3], Jani Kotakoski[1], Tracy Clark Lovejoy[2], Clemens Mangler[1], Andreas Mittelberger[2], Timothy J. Pennycook[3], Benjamin Plotkin-Swing[2]
[1]University of Vienna, Faculty of Physics, Vienna, Austria, [2]Nion Co. R&D, Kirkland, USA, [3]EMAT, University of Antwerp, Antwerp, Belgium

86 A Secondary Electron Hyperspectral Imaging characterisation of mechanochemically functionalised carbon black materials

James Nohl[1,2], Nicholas Farr[1], Maria Rosaria Acocella[3], Serena Cussen[4], Cornelia Rodenburg[1]
[1]Department of Materials Science and Engineering, The University of Sheffield, Mappin Street, Sheffield, UK, [2]The Faraday Institution, Quad One, Becquerel Avenue, Harwell Campus, Didcot, UK, [3]Department of Chemistry and Biology " A. Zambelli", University of Salerno, Via Giovanni Paolo II, 132- 84084 Fisciano, Italy, [4]School of Chemistry, University College Dublin, Belfield, Dublin 4, Ireland

87 Temperature-driven in-situ TEM cation exchange at the solid state: a combined experimental and computational study

Alberto Casu[1], Mr. Claudio Melis[2], Mr. Luciano Colombo[2], Mr. Andrea Falqui[1,3]
[1]Department of Physics, University of Milan, Milan, Italia, [2]Department of Physics, University of Cagliari, Monserrato, Italy, [3]Interdisciplinary Centre for Nanostructured Materials and Interfaces (CIMaINa)- Department of Physics, University of Milan, Milan, Italy

88 Advanced electron microscopy study of Cu coated Boron Nitride sheets

NITUL Rajput[1], Mr Abdullah Al Shehhi[1], Dr Monserrat Gutierrez[1], Dr Afra Al Ketbi[1]
[1]Technology Innovation Institute, Masdar, United Arab Emirates

89 Second harmonic generation microscopy of femtosecond microstructured crystals

Nuria Sevilla Sierra[1,2], Dr. Javier Rodríguez Vázquez de Aldana[1,2], Dr. Carolina Romero[1,2], Dr. Xavier Mateos[3], Dr. Ignacio Lopez-Quintas[1,2]
[1]Grupo de Investigación en Aplicaciones del Láser y Fotónica, Universidad de Salamanca (USAL), Salamanca, Spain, [2]Unidad de Excelencia en Luz y Materia Estructurada (LUMES), Universidad de Salamanca, Salamanca, Spain, [3]Física i Cristal·lografía de Materials (FiCMA), Universitat Rovira i Virgili (URV), Tarragona, Spain

90 Latest developments in accurate and high-throughput correlative cryo-FIB milling for cryo-ET lamella production

Marit Smeets[1], Deniz Daviran[1], Wessel Teunisse[1]
[1]Delmic B.V., Delft, The Netherlands

91 A Novel Tool for Combined AFM, SEM, and Electrical Probing of Nanostructures

Chris Schwalb[1], Mr. Hajo Frerichs[1], Mr. Darshit Jangid[1], Mr. Sebastian Seibert[1], Mr. Lukas Stühn[1], Mrs. Marion Wolff[1], Mr. Andrew Jonathan Smith[2], Mr. Andreas Rummel[2]
[1]Quantum Design Microscopy GmbH, Pfungstadt, Germany, [2]Kleindiek Nanotechnik GmbH, Reutlingen, Germany

92 TEM Investigations on the Impact of Hydrogen on Phase Transformations in Aluminum Alloys

M. Omar Boukir[1], M. Xavier Sauvage[1], M. Kaveh Edalati[2]
[1]Univ Rouen Normandie, INSA Rouen Normandie, CNRS, Groupe de Physique des Matériaux UMR 6634, F-76000, Rouen, France, [2]2WPI, International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, Fukuoka 819-0395,, Fukuoka, Japan

93 Contribution of Probiotics to the Effect of Platelet-Rich Plasma in Diabetic Rat Skin Wound Healing

Prof. Dr. Erdogan Kocamaz, Prof. Dr. Muge Karakayali, PhD Fatih Collu, Prof. Dr. Sevinc Inan, Prof. Dr. Ibrahim Tuglu
[1]Department of Histology and Embryology, Manisa Celal Bayar University, Faculty of Medicine, Manisa, Turkey, [2]Department of Microbiology, Izmir Democracy University, Faculty of Medicine, Izmir , Turkey, [3]Department of Zoology, Manisa Celal Bayar University, Faculty of Life Sciences, Manisa, Turkey, [4]Department of Histology and Embryology, Izmir University of Economics, Faculty of

Medicine, Izmir, Turkey, [5]Department of Histology and Embryology, Manisa Celal Bayar University, Faculty of Medicine, Manisa, Turkey

94 Asbestos Analytics In Relation To Changes Of The European Directive

Bianca Gasse[1]
[1]Institute for Occupational Safety and Health of the German Social Accident Insurance, Sankt Augustin, Germany

95 Quantum Wavefront Shaping with a 48-element Programmable Phase Plate for Electrons

Francisco Vega[1,2], Dr. Chu-Ping Yu[1,2], Dr. Armand Béché[1,3], Prof. Dr. Jo Verbeeck[1,2]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [3]AdaptEM, Heverlee,, Belgium

96 Characterisation of Skyrmion Spin Textures in CoB/CoFeB Multilayers

Colin Kirkbride[1], Dr Razan Aboljadayel[2], Dr Kayla Fallon[1], Ms Sara Villa[1], Dr Trevor Almeida[1], Prof. Marrows CH[2], Prof. Stephen McVitie[1]
[1]University of Glasgow, Glasgow, United Kingdom, [2]University of Leeds, Leeds, United Kingdom

97 Exploring the limits of 3D ED for accurate structure analysis at the nanometer scale

Ms Sara Passuti[1], Ms Erica Cordero Oyonarte[1], M Valérie Pralong[1], M Adrian David[1], M Emmanuel Guilmeau[1], M Lukas Palatinus[2], Mr. Philippe Boullay[1]
[1]Normandie Université, ENSICAEN, UNICAEN, CNRS, CRISMAT, Caen, France , [2]Czech Academy of Sciences, Department of Structure Analysis, Na Slovance 2, Prague, Czechia

98 Multiparametric investigation of bacterial surface structure with correlative atomic force microscopy

Dr. Joan Carles Escolano[1], Torsten Müller[1], André Körnig[1], Thomas Henze[1]
[1]JPK BioAFM, Bruker Nano GmbH, Berlin, Germany

99 Silicide precipitation in aged quasi-α Ti alloys

Dr Frédéric Fossard[1], Mr. Thibaut Armanni[2], Mr. Thierry Douillard[3], Mr. Jean-Sébastien Mérot[1], Mr. Benoît Appolaire[4]
[1]Université Paris-Saclay, ONERA, CNRS, LEM, Châtillon, France, [2]Université Paris Saclay, ONERA, Matériaux et Structures, Châtillon, France, [3]INSA Lyon, Université de Lyon, MATEIS, UMR CNRS 5510, Villeurbanne, France, [4]Université de Lorraine, CNRS, Institut Jean Lamour, Nancy, France

100 Enhanced imaging for serial Cryo-FIB-SEM microscopy of biological samples with fluorescence navigation

Pavel Krepelka[1], Jana Moravcova[1], Jiri Novacek[1]
[1]Central European Institute of Technology, Masaryk University, Brno, Czech Republic

101 High-throughput laboratory-based scattering X-ray Tensor Tomography

Azat Slyamov[1], Mr. Adriaan van Roosmalen[1], Mr. Kenneth Nielsen[1], Mr. Erik Lauridsen[1]
[1]Xnovo Technology ApS, Køge, Denmark

102 Achieving atomic precision 3D reconstructions through Bayesian genetic optimisation

Mr. Tom Stoops[1,2], Dr. Annick De Backer[1,2], Prof. Dr. Sandra Van Aert[1,2]
[1]EMAT, University of Antwerp, , Belgium, [2]NANOlab Center of Excellence, University of Antwerp, , Belgium

103 End-to-end learning of atomic resolution phase-contrast volumes from 4D-STEM measurements

Shengbo You[1], Dr Andrey Romanov[1], Dr Philipp Pelz[1]
[1]Institute of Micro- and Nanostructure Research (IMN) & Center for Nanoanalysis and Electron Microscopy (CENEM), Friedrich Alexander-Universität Erlangen-Nürnberg,, Erlangen, Germany

104 Mapping Orthorhombic Domains with Geometrical Phase Analysis

Bernat Mundet[1], Mr. Marios Hadjimichael[2], Jennifer Fowlie[3], Lukas Korosec[4], Lucia Varbaro[4], Claribel Domínguez[4], Prof. Jean-Marc Triscone[4], Duncan Alexander

[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), Bellaterra, Spain, [2]Department of Physics, University of Warwick, Warwick, United Kingdom, [3]Stanford University, Stanford, USA, [4]Department of Quantum Matter Physics, University of Geneva, Geneva, Switzerland, [5]Electron Spectrometry and Microscopy Laboratory (LSME), Institute of Physics (IPHYS), École Polytechnique Fédérale de Lausanne ole Polytechnique Federal de Lausanne (EPFL), Lausanne, Switzerland

105 Localized, anodic aluminum corrosion phenomena studied with electrochemical liquid phase electron microscopy

Morgan Binggeli Barbey[1], Prof. Vasiliki Tileli[1]
[1]Ecole polytechnique fédérale de Lausanne (EPFL), Lausanne, Switzerland

106 In-situ SEM Correlated Nanoindentation and Electrical Nanoprobing

Renato Pero[1], Ms. Anya Grushina[2], Mr. Nicholas Randall[1], Mr. Jean-Marc Breguet[1], Mr. Guillaume Boetsch[2]
[1]Alemnis AG, Schorenstrasse 39, 3645,Thun, Switzerland, [2]Imina Technologies, Rte de Montheron 8B, 1053 Cugy, Switzerland

107 In-situ Extreme Mechanics – Recent Innovations and Prospects

Mr. Nicholas Randall[1], Renato Pero[1], Mr. Jean-Marc Breguet[1]
[1]Alemnis AG, Schorenstrasse 39, 3645,Thun, Switzerland

108 MIPAR Spotlight: Shedding Light on Next-Generation Detection for Microscopists

CEO Sammy Nordqvist[1], Mr Sammy Nordqvist[2], Dr John Sosa[1], Mr Michael Kudlinski[1]
[1]MIPAR Image Analysis Software, Columbus, United States, [2]SciSpot, Stenungsund, Sweden

109 Enhancing quantifiability of S/TEM-based composition mappings through correlative techniques

Kai-luis Jakob[1], Mr. Frederik Otto[1], Dr. Dirk Berger[2], Dr. Tore Niermann[1], Prof. Dr. Michael Lehmann[1]
[1]Technische Universität Berlin, Institute of Optics and Atomic Physics, Berlin, Germany, [2]Technische Universität Berlin, Zentraleinrichtung Elektronenmikroskopie (ZELMI), Berlin, Germany

110 Confined single-molecule imaging by low-dose electron microscopy

Huiqiu Wang[1,2], Prof. Xiaodong Zou[1]
[1]Department of materials and environmental chemistry, Stockholm University, Stockholm, Sweden, [2]Department of chemical engineering, Tsinghua University, Beijing, China

111 Exploring novel joining technique of Gas Actuated Bonding by utilizing In-situ Environmental-TEM

Dr. Rahul Bhattacharya[1], Dr. Martin Ek[1], Dr. Filip Lenrick[1]
[1]LTH, Lund University, Lund, Sweden

112 3D Investigation of Lath Martensite in a Low-Carbon Stainless Steel Using PFIB-EBSD Tomography

Mehdi Mosayebi[1], Mr Daniel Paquet[2], Mr Pierre-Antony Deschênes[2,3], Mr Laurent Tôn-Thât[2], Dr Nabil Bassim[1,4]
[1]Materials Science and Engineering Department, Hamilton, Canada, [2]Hydro-Québec, Hydro-Québec Research Institute, Varennes, Canada, [3]Mechanical Engineering Department, École de technologie supérieure, Montreal, Canada, [4]Canadian Centre for Electron Microscopy, McMaster University, Hamilton, Canada

113 Determining alloy concentration by analyzing dynamic diffraction at strained semiconductor interfaces

Frederik Otto[1], Dr. Laura Niermann[1], Dr. Tore Niermann[1], Prof. Dr. Michael Lehmann[1]
[1]Technische Universität Berlin, Berlin, Germany

114 Electronic properties of W' twin domain walls in ferroelastic BiVO4

Yuwen Xu[1], Dr. Pankaj Sharma[2,3,4], Mr. Haotian Wen[1], Mr. Dawei Zhang[1,2], Dr. Charlie Kong[5], Dr. Zewu Yan[6], A/Prof. Shery L.Y. Chang[1,5], Prof. Jan Seidel[1,2]
[1]School of Materials Science and Engineering, UNSW Sydney, Sydney, Australia, [2]ARC Centre of Excellence in Future Low-Energy Electronics Technologies (FLEET), UNSW Sydney, Sydney, Australia, [3]College of Science and Engineering, Flinders University, Bedford Park, Australia, [4]Flinders Institute

for Nanoscale Science and Technology, Flinders University, Adelaide, Australia, [5]Electron Microscope Unit, Mark Wainwright Analytical Centre, UNSW Sydney, Sydney, Australia, [6]Laboratorium für Festkörperphysik, ETH Hönggerberg, Zürich, Switzerland

115 Electron Videography and Machine Learning of Soft Matter

Prof. Qian Chen[1], Lehan Yao

[1]Department of Materials Science and Engineering, University of Illinois, Urbana, United States

116 High-resolution STEM Image Acquisition Method for Tilted Specimen Using a New Type of Aberration Corrector

Wataru Koibuchi[1], Mr. Ryusuke Sagawa[1]

[1]JEOL, Akishima, JAPAN

117 Simultaneous Acquisition of 4D and EELS Data by Newly Developed Pixelated STEM Detector

Dr. Ryusuke Sagawa[1], Mr. Hiroki Hashiguchi[1], Mr. Akiho Nakamura[1], Ms. Shoko Shibagaki[1], Mr. Yutaka Kazama[1], Mr. Martin Huth[2], Mr. Yassine Imari[2], Mr. Valentin Kroner[2], Mr. Stefan Aschauer[2]

[1]JEOL Ltd., Akishima, Japan, [2]PNDetector GmbH, München, Germany

118 Development of planar micro optics for ultrafast in-situ measurements in the TEM

Max Herzog[1,2], Dr. Johannes Schultz[1], Prof. Dr. Axel Lubk[1,3]

[1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany, [2]TUD Dresden University of Technology, Dresden, Germany, [3]Institute of Solid State and Materials Physics of TUD, Dresden, Germany

119 Unveiling Metal-Insulator Transitions in (V1-xCrx)2O3 through in situ Monochromatized STEM/EELS

Dr. Abdelali Khelfa[1], Mr. Jean-Denis Blazit[1], Mr. Luiw H. G. Tizei[1], Mr. Etienne Janod[2], Mr. Julien Tranchant[2], Mr. Benoît Corraze[2], Mr. Laurent Cario[2], Mrs. Odile Stephan[1], Mrs. Laura Bocher[1]

[1]Laboratoire de Physique des Solides - Université Paris Saclay - CNRS, Orsay (91405), France, [2]Institut des Matériaux Jean Rouxel - Université de Nantes - CNRS, Nantes (44322), France

120 Depth Dependence of Electron Channeling Contrast Imaging in Gallium Nitride

Etienne Lavallee[1,2], Mr. Antoine Guitton[2], Mr. Peter Imrich[1], Ms. Claire Chisholm[1]

[1]KAI Kompetenzzentrum Automobil-und Industrieelektronik GmbH, 9524 Villach, Austria, [2]Université de Lorraine, CNRS, Arts et Métiers, LEM3, Metz, France

121 Multidimensional Characterisation and Multivariate Analysis of Cu3P Nanocages for Catalysis

Dr. Andrea Griesi[1], Mr. Rundong Mao[2], Mr. Sirous Khabbazabkenar[1], Mr. Yurii Ivanov[1], Mr. Guohua Jia[2], Mr. Giorgio Divitini[1]

[1]Ististuto Italiano di Tecnologia, Genova, Italy, [2]Curtin University , Perth, Australia

122 Universal Laser Engine:
A microscope illumination that combines FLIM and homogenized powerful wide-field lasers

Daniel Schröder[1,2], Philipp Wendelberger[3], Dr. Oleksii Nevskyi[4], Alexander Seltmann[2], Francisco Paez[1,2], Anindita Dasgupta[1,2], John Wigg[3], Dr. Philipp Hoess[5], Dr. Jonas Ries[5], Dr. Jerome Wenger[6], Dr. Emmanuel Margeat[7], Dr. Jörg Enderlein[4], Dr. Christian Eggeling[1,2]

[1]Leibniz Institute of Photonic Technology, Jena, Germany, [2]Institute of Applied Optics and Biophysics, Friedrich Schiller University, Jena, Germany, [3]Physics and Astronomy, Friedrich Schiller University, Jena, Germany, [4]Physics, Third Institute of Physics Biophysics, Georg-August-Universtät, Göttingen, Germany, [5]Cell Biology and Biophysics, European Molecular Biology Laboratory, , Germany, [6]Aix Marseille Univ, CNRS, Centrale Marseille, Institut Fresnel, AMUTech, Marseille, France, [7]Centre National de la Recherche Scientifique, Institut National de la Santé et de la Recherche Médicale, Université Montpellier, Centre de Biologie Structurale, Montpellier, France

123 Quantitative chemical analysis by STEM-EDS and machine learning: Are AgAu alloyed at the nanoscale?

Dr Murilo Moreira[1,2], Dr. Emmanuel Cottancin[1], Dr. Michel Pellarin[1], Dr. Lucian Roiban[3], Dr. Karine Massenelli-Varlot[3], Dr. Daniel Ugarte[2], Dr. Varlei Rodrigues[2], Dr. Matthias Hillenkamp[1,2]
[1]Institute of Light and Matter, University Lyon, University Claude Bernard Lyon 1, CNRS, UMR5306, Villeurbanne F-69622, France, [2]Institute of Physics Gleb Wataghin, State University of Campinas, Campinas, 13083-970, Brazil, [3]INSA Lyon, Universite Claude Bernard Lyon 1, CNRS, MATEIS, UMR5510, Villeurbanne , France

124 Visualizing alloying in Au-Pd core-shell nanoparticles using in situ gas-phase transmission electron microscopy

Marta Perxés Perich[1], Christopher R. O'Connor[2], Koen M. Draijer[1], Nienke L. Visser[1], Nongnuch Artrith[1], Christian Reece[2], Petra E. de Jongh[1], Jessi E. S. van der Hoeven[1]
[1]Materials Chemistry and Catalysis, Debye Institute for Nanomaterials Science, Utrecht University, Utrecht, The Netherlands, [2]Rowland Institute at Harvard, Harvard University, Cambridge, USA

125 Cryogenic scanning electron microscopy of hereditary hemolytic anemias

Irina Davidovich[1], Mrs. Carina Levin[2,3], Mr. Yeshayahu Talmon[1]
[1]Department of Chemical Engineering and the Russell Berrie Nanotechnology Institute (RBNI), Technion-Israel Institute of Technology, Haifa, Israel, [2]Pediatric Hematology Unit, Emek Medical Center , Afula, Israel, [3]Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel

126 Physics-based synthetic data model for automated segmentation in catalysis microscopy

Maurits Vuijk[1,2], Dr. Gianmarco Ducci[1], Dr. Luis Sandoval[2], Dr. Thomas Lunkenbein[2], Dr. Christoph Scheurer[1], Prof. Dr. Karsten Reuter[1]
[1]Fritz-Haber-Institut, Theory Department, Berlin, Germany, [2]Fritz-Haber-Institut, AC Department, Berlin, Germany

127 Tri-layer graphene as membrane and electrode for liquid-phase electron microscopy studies of CO2 electroreduction nanocatalysts

Saltanat Toleukhanova[1], Dr. Tzu-Hsien Shen[1], Mr Chen Chang[1], Miss. Swathilakshmi Swathilakshmi[1], Miss. Tecla Bottinelli Montandon[1], Prof. Vasiliki Tileli[1]
[1]Institute of Materials, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

128 Unraveling the True 3D Structure of Colloidal Assemblies by Liquid Cell Electron Tomography

Daniel Arenas Esteban[1], Dr. Da Wang[1,2], Dr. Ajinkya Kadu[1,3], Mr. Noa Olluyn[1], Dr. Ana Sanchez Iglesias[4,5,6], Dr. Alejandro Gomez-Perez[7], Dr. Jesús Gonzalez Casablanca[8], Dr. Stavros Nicolopoulos[7], Prof. Luis M. Liz-Marzán[4,5,9,10], Prof. Sara Bals[1]
[1]Electron Microscopy for Materials Science (EMAT) and NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [2]Guangdong Provincial Key Laboratory of Optical Information Materials and Technology, South China Normal University, Guangzhou, China, [3]Centrum Wiskunde & Informatica (CWI), Amsterdam, The Netherlands, [4]CIC biomaGUNE, Donostia-San Sebastián, Spain, [5]Centro de Investigación Biomédica en Red, Bioingeniería, Biomateriales y Nanomedicina, CIBER-BBN, Donostia-San Sebastián, Spain, [6]Centro de Física de Materiales CSIC-UPV/EHU, Donostia-San Sebastián, Spain, [7]NanoMEGAS SRPL, Brussels, Belgium, [8]Universidad Rey Juan Carlos, Centro de Apoyo Tecnológico, Madrid, Spain, [9]Ikerbasque, Basque Foundation for Science, Bilbao, Spain, [10]Cinbio, Universidade de Vigo, Vigo, Spain

129 Exploring solid conversion products in lithium-sulfur batteries through cryo-TEM and machine-learning-supported small angle neutron scattering

Jean-marc Von Mentlen[1], Mrs. Ayca Senol[1], Mr. Thomas Demuth[3], Dr. Jürgen Belz[3], Dr. Alen Vižintin[4], Prof. Dr. Kerstin Volz[3], Prof. Dr. Vanessa Wood[1], Prof. Dr. Christian Prehal[2]
[1]ETH Zurich, Zurich, Switzerland, [2]Paris Lodron University Salzburg, Salzburg, Austria, [3]Phillips University Marburg, Marburg, Germany, [4]National Institute of Chemistry, Ljubljana, Slovenia

130 A new Ion Microscope for high-resolution imaging and SIMS nano-analytics

Dr. Alexander Ost[1], Torsten Richter[1], Olivier De Castro[2], Peter Gnauck[1], Jean-Nicolas Audinot[2], Tom Wirtz[2]
[1]Raith GmbH, Dortmund, Germany, [2]Luxembourg Institute of Science and Technology (LIST), Belvaux, Luxembourg

131 Understanding Twinning and Hierarchical Structure of Synthetic Guanine with 4D-Scanning Transmission Electron Microscopy

Rebekka Klemmt[1], Christian Lund Rasmussen[1], Ass. Prof. Espen Draht Bøjesen[1], Prof. Henrik Birkedal[1]
[1]Interdisciplinary Nanoscience Center (iNANO), Aarhus University, Aarhus, Denmark

132 Developing alloys presenting nanograins and spinodal decomposition: structural and compositional characterization

Juan Macchi[1], Olha Nakonechna[2], Ronan Henry[1], Celia Castro[1], Kaveh Edalati[2], Frederic De Geuser[3], Xavier Sauvage[1], Williams Lefebvre[1]
[1]Univ Rouen Normandie, INSA Rouen Normandie, CNRS, Normandie Univ, GPM UMR 6634, Rouen, France, [2]WPI, International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University,, Fukuoka, Japan, [3]University Grenoble Alpes, CNRS, Grenoble INP, SIMaP, Grenoble , France

133 Insights into the degradation of nanocatalysts under fuel cell conditions by 3D identical location STEM

Senior Researcher Alba Garzon Manjon[1], Mr Miquel Vega Paredes[2], Miss Raquel Aymerich Armengol[2], Mr Daniel Arenas Esteban[3], Miss Sara Martí Sánchez[1], Miss Sara Bals[3], Miss Christina Scheu[2]
[1]Institut Català de Nanociència i Nanotecnologia, Bellaterra, Barcelona, [2]Max Planck Institut für Eisenforschung GmbH, Düsseldorf, Germany, [3]University of Antwerpen - Electron microscopy for materials science, Amtwerpen, Belgium

134 Structure analysis on the nm scale: The amorphous LiNbO3 coatings for solid state batteries

Johannes Haust[1], Dr. Jürgen Belz[1], Dr. Shamail Ahmad[1], Mrs. Narges Adeli[1], Mrs. Franziska Hüppe[1], Mrs. Yiran Guo[2], Mr. Linus Erhard[3], Dr. Jochen Rohrer[3], Dr. Anna-Lena Hansen[2], Dr. Valeriu Mereacre[2], Prof. Dr. Karsten Albe[3], Prof. Dr. Kerstin Volz[1]
[1]Philipps University Marburg, Marburg , Germany, [2]Karlsruhe Institute of Technology, Karlsruhe, Germany, [3]Technical University of Darmstadt, Darmstadt, Germany

135 Secondary envelopment of the human cytomegalovirus is a fast process, utilizing the endocytic compartment

Tim Bergner[1], Laura Cortez Rayas[2], Jens von Einem[2], Dr. Clarissa Read (Villinger)[1]
[1]Central Facility for Electron Microscopy, Ulm University, Ulm, Germany, [2]Institute of Virology, Ulm University Medical Center, Ulm, Germany

136 An accessible Secondary Electron Hyperspectral Imaging approach to draw meaningful insights from scanning electron microscopy

James Nohl[1,2], Jingqiong Zhang[1], Lyudmila Mihaylova[1], Serena Cussen[3], Cornelia Rodenburg[1]
[1]Department of Materials Science and Engineering, The University of Sheffield, Mappin Street, Sheffield, UK, [2]The Faraday Institution, Quad One, Becquerel Avenue, Harwell Campus, Didcot, UK, [3]School of Chemistry, University College Dublin, Belfield, Dublin 4, Ireland

137 High-throughput tomography correlated with light and electron microscopy for multi-scale imaging of human kidney tissue

Dr. Matthew Lawson[1], Alana Burrell[2], Jonas Albers[1], Xioafan Xiong[3], Virginie Uhlmann[3], Yannick Schwab[4], Candice Roufosse[5], Lucy Collinson[2], Elizabeth Duke[1]
[1]European Molecular Biology Laboratory Hamburg Unit, Hamburg, Germany, [2]The Francis Crick Institute, London, United Kingdom, [3]European Bioinformatics Institute, Cambridge, United Kingdom,

[4]European Molecular Biology Laboratory, Heidelberg, Germnay, [5]Imperial College London, London, United Kingdom

138 In Situ Study of Self-Organized Memristive Switching in Neuromorphic Nanoparticle Networks using Complementary SEM Methods

Ole Gronenberg[1], Mrs. Blessing Adejube[2], Mr. Torben Hemke[3], Dr. Niko Carstens[3], Mr. Oguz Han Asnaz[4], Dr. Ulrich Schürmann[1,6], Dr. Thomas Strunskus[2,6], Dr. Franz Faupel[2,6], Dr. Thomas Mussenbrock[3], Dr. Jan Benedikt[4,6], Dr. Alexander Vahl[2,5,6], Dr. Lorenz Kienle[1,6]
[1]Department of Materials Science – Synthesis and Real Structure, Faculty of Engineering, Kiel University, Kiel, Germany, [2]Department of Materials Science – Chair for Multicomponent Materials, Faculty of Engineering, Kiel University, Kiel, Germany, [3]Chair of Applied Electrodynamics and Plasma Technology (AEPT), Ruhr University Bochum, Bochum, Germany, [4]Experimental Plasma Physics, Institute of Experimental and Applied Physics, Kiel University, Kiel, Germany, [5]Leibniz Institute for Plasma Science and Technology, Greifswald, Germany, [6]Kiel Nano Surface and Interface Science KiNSIS, Kiel University, Kiel, Germany

139 Suppression of Stacking Faults for Stable Cesium-Formamidinium Perovskite Absorbers

Mr Mostafa Othman[1], Mr. Quentin Jeangros[2], Mrs Anaël Jaffrès[2], Mr Victor Boureau[3], Mrs Sandra Jenatsch[4], Mr Beat Ruhstaller[4], Mr Christophe Ballif[1,2], Mr Christian Wolff[1], Aïcha Hessler-Wyser[1]
[1]Photovoltaics and thin-film electronics laboratory (PV-Lab), École Polytechnique Fédérale de Lausanne (EPFL), 2000 Neuchâtel, Switzerland, [2]CSEM, Sustainable Energy Center, 2000 Neuchâtel, Switzerland, [3]Centre Interdisciplinaire de Microscopie Electronique (CIME), EPFL, 1015 Lausanne, Switzerland, [4]Fulxim AG, 8400 Winterthur, Switzerland

140 Using secondary electron electron beam induced current for characterization of nanoparticle morphologies

Dr. Evgenii Vlasov[1,2], Mr. Wouter Heyvaert[1,2], Dr. Robin Girod[1,2], Prof. Luis M. Liz-Marzán[3], Prof. Johan Verbeeck[1,2], Prof. Sara Bals[1,2]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [3]CIC biomaGUNE, Basque Research and Technology Alliance (BRTA), Donostia-San Sebastián, Spain

141 Development and characterization of N2O-plasma oxide layers for high-temperature passivating contacts solar cells

Mrs Sofia Libraro[1], Mr Lars Bannenberg[2], Mr Theodosios Famprikis[2], Mr David Reyes[3], Mr Julien Hurni[1], Mr Christophe Ballif[1,4], Mr Franz-Josef Haug[1], Mrs Audrey Morisset[1], Aïcha Hessler-Wyser[1]

149 Strain Sensitivity of STEM-GPA-based Strain Map
Bumsu Park[1], Minsik Kim[1], Jiwon Jeong[1], Sungho Lee[1]
[1]Samsung Electronics Advanced Analysis Science & Engineering Team, Hwaseong-si/Samnsungjeonja-ro, Republic of Korea
150 A retractable, compact Secondary Electron Energy Spectrometer attachment for Scanning Electron Microscopes
Wenzheng Cao[1], Prof. Anjam Khursheed[1]
[1]Politecnico di Milano, Milan, Italy
151 Approaching picosecond temporal resolution in off-axis electron holography
Dr. Tolga Wagner[1], Hüseyin Çelik[2], Simon Gaebel[3], Dirk Berger[4], Christian M. Günther[4], Ines Häusler[1], Sebastian Siewert[2], Michael Lehmann[2], Christoph T. Koch[1]
[1]Department of Physics, Humboldt-Universität zu Berlin, Berlin, Germany, [2]Institute of Optics and Atomic Physics, Technische Universität Berlin, Berlin, Germany, [3]Max-Born-Institut, Berlin, Germany, [4]Center for Electron Microscopy (ZELMI), Technische Universität Berlin, Berlin, Germany

152 Synthetic data generation and Mask-RCNN for Transmission Electron Microscope Image Segmentation
Natalia Da Silva De Sa[1], Dr. Andrew Stewart[2]
[1]University of Limerick, Limerick, Ireland, [2]University College London, London, United Kingdom
153 Probing chemical pathways in polymer membranes despite electron beam damage
Dr Catriona M. McGilvery[1], Dr Patricia Abellan[2], Prof Quentin M. Ramasse[3], Prof Alexandra E. Porter[1]
[1]Imperial College London, London, UK, [2]CNRS-Nantes University, Nantes, France, [3]SuperSTEM Laboratory, Daresbury, UK
154 Oxidation states of IrOx characterised by EELS and ED-PDF
Dr. Trung-Dung Tran[1,2], Mr. Dogan Ozkaya[1,2]
[1]Johnson Matthey Technology Centre, Reading, UK, [2]ePSIC, Diamond Light Source, Didcot, UK
155 Atom Probe Tomography experiments performed in a (Scanning) Transmission Electron Microscope
Professor Williams Lefebvre[1], Gérald Da Costa[1], Castro Celia[1], Antoine Normand[1], Charly Vaudolon[1], Aidar Zakirov[1], Juan Macchi[1], Mohammed Ilhami[1], François Vurpillot[1]
[1]Univ Rouen Normandie, INSA Rouen Normandie, CNRS, Normandie Univ, GPM UMR 6634, Rouen, France
156 Opening the third dimension to your SEM with integrated fs-laser
Olena Vertsanova[1,2], Dr. Sabine Lenz[1], Martina Heller[1], Sebastian Krauss[1]
[1]Carl Zeiss Microscopy GmbH, Oberkochen, Germany, [2]National Technical University of Ukraine “KPI”, Kyiv, Ukraine
157 Unique in-situ characterization workflow of Cathode Components using AFM-in-SEM
Veronika Hegrova[1], Mr. Radek Dao[1], Dr. Vojtech Schanilec[1], Dr. Jan Neuman[1]
[1]NenoVision s. r. o., Brno, Czech Republic
158 Breaking barriers: Innovative methods for 4DSTEM diffraction data acquisition and processing in SEM
Nikita Denisov[1], Mr. Andrey Orekhov[1], Mr. Johan Verbeeck[1]
[1]EMAT, University of Antwerp, Antwerp, Belgium
159 Unraveling point defects and moiré patterns in liquid exfoliated PtSe2
Ilias-panagiotis Oikonomou[1,2,3], Dr. Danielle Douglas-Henry[1,2], Dr. Thomas Brumme[3], Prof. Zdenek Sofer[4], Prof. Thomas Heine[3,5], Prof. Valeria Nicolosi[1,2]
[1]Advanced Microscopy Laboratory, CRANN and AMBER centres, Dublin 2, Ireland, [2]Trinity College Dublin, School of Chemistry, Dublin 2, Ireland, [3]TU Dresden, Chair of Theoretical Chemistry, Dresden, Germany , [4]University of Chemistry and Technology Prague, Dept. of Inorganic Chemistry, Prague, Czech Republic , [5]Center for Advanced Systems Understanding (CASUS), Görlitz, Germany
160 Structural characterization of the active and inactive conformations of the vasopressin V2 receptor using cryo-EM
Aurelien Fouillen[1,2], Mr. Bous Julien[1,2], Mrs Helene Orcel[1], Mr Stefano Trapani[2], Mrs Xiaojing Cong[1], Mrs Juliette Dimon[1], Mr Simon Fontanel[1], Mrs Julie Saint-Paul[1], Mrs Josephine Lai-Kee-Him[2], Mr Serge Urbach[1], Mr Remy Sounier[1], Mr Patrick Bron[2], Mr Sebastien Granier[1], Mr Bernard Mouillac[1]
[1]Institut de Génomique Fonctionnelle , Montpellier, France, [2]Centre de Biologie Structurale, Montpellier, France
161 MicroReactor for battery materials synthesis in SEM
Libor Novak[1], Mr. Vojtěch Kundrát[2], Mr. Petr Hlavenka[1]
[1]Thermo Fisher Scientific, Brno, Czechia, [2]Weizmann Institute of Science, Rehovot, Israel
162 Liquid Phase Transmission Electron Microscopy
Mads Søndergaard Larsen[1], Mr Ebrahim Chalangar[1], Mrs Sofie Tidemand-Lichtenberg[1], Mr Murat Nulati Yesibolati[1], Mr. Emil Jensen[1], Mr. Kristian Speranza Mølhave[1]

[1]DTU Nanolab, Kgs. Lyngby, Denmark

163 EELS at Extreme Energy Losses; complementary Information to X-ray Absorption Spectroscopy (XAS) in a TEM

Dr Sorin Lazar[1], Mrs. Maria Meledina[1], Mrs. Claudia S. Schnohr[2], Mr. Thomas Hoeche[3], Mr. Peter Tiemeijer[1], Mr. Paolo Longo[1], Mr. Bert Freitag[1]
[1]Thermo Fisher Scientific, Eindhoven, Netherlands, [2]Felix Bloch Institute for Solid State Physics, Leipzig, Germany, [3]Fraunhofer-Institut für Mikrostruktur von Werkstoffen und Systemen IMWS, Halle (Saale), Germany

164 Structure Prediction using Data Derived Potentials and EELS

Thomas Ginnis[1], Professor Rebecca J Nicholls[1], Professor David Armstrong[1]
[1]Department of Materials, University of Oxford, Oxford, United Kingdom

165 Assessing the sensitivity of 4D-STEM measurements for electric field mapping at the sub-micrometer scale

Pierpaolo Ranieri[1], Dr. Reinis Ignatans[1], Dr. Victor Boureau[2], Prof. Vasiliki Tileli[1]
[1]Institute of Materials, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, [2]Interdisciplinary Centre for Electron Microscopy, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

166 In situ TEM/EELS and spatially resolved XAS/XRF analysis of CuO electrocatalyst for CO2 reduction

Dr Manfred Erwin Schuster[1], Dr Gea T. van de Kerkhof[2], Dr Angela E. Goode[1], Dr Urša Podbevšek[1]
[1]Johnson Matthey, Sonning Common, United Kingdom, [2]Diamond Light Source, Didcot, United Kingdom

167 Epitaxially-assisted Sn Crystal Phase Selectivity on Hybrid Superconductor-Semiconductor Quantum Nanowires

Sara Martí-Sánchez[1], Dr Sabbir A. Khan[2], Prof Peter Krogstrup[3], Prof Jordi Arbiol[4]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Bellaterra, Spain, [2]Danish Fundamental Metrology, Copenhaguen, Denmark, [3]NNF Quantum Computing Programme, Niels Bohr Institute, University of Copenhagen, Copenhaguen, Denmark, [4]ICREA, Barcelona, Spain

168 Structure of the first isolated polinton-like virus and its host

Dr. Gabriela N. Condezo[1], Mr. Roberto Marabini[2], Mr. Javier Conesa[1], Mr. David Delgado[1], Mrs. Hilde K. Stabell[3], Mr. Gunnar Bratbak[3], Mrs. Carmen San Martín[1]
[1]Centro Nacional de Biotecnología (CNB-CSIC), Madrid, Spain, [2]Escuela Politécnica Superior. Universidad Autónoma de Madrid, Madrid, Spain, [3]Department of Biology. University of Bergen, Bergen, Norway

169 Correlative analytical scanning electron microscopy reveals periprosthetic tissue response to nanoparticles and wear debris

Dr Louise Hughes[1], Pedro Machado[1], Joshua Lea[1], Zhidao Xia[2]
[1]Oxford Instruments NanoAnalysis, High Wycombe, UK, [2]Swansea University, Swansea, UK

170 Structural and metabolic dynamics of plant cells in context of heat acclimation

Charlotte Seydel[1,3], Prof. Dr. Martin Heß[2], Prof. Dr. Thomas Nägele[3], Prof. Dr. Andreas Klingl[1]
[1]Ludwig-Maximilians-Universität München, Faculty of Biology, Plant Development, Planegg-Martinsried, Germany, [2]Ludwig-Maximilians-Universität München, Faculty of Biology, Systematic Zoology, Planegg-Martinsried, Germany, [3]Ludwig-Maximilians-Universität München, Faculty of Biology, Plant Evolutionary Cell Biology, Planegg-Martinsried, Germany

171 Open top dual-view light-sheet microscope for live imaging of large multicellular systems

Franziska Moos[1,2], Simon Suppinger[1,2], Gustavo de Medeiros[1,3], Koen Oost[1], Andrea Boni[3], Camille Rémy[3], Sera Weevers[1,2], Charisios Tsiairis[1,2], Petr Strnad[3], Prisca Liberali[1,2]

[1]Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Viventis Microscopy Sàrl, Lausanne, Switzerland

172 Quantitative Analysis of Magnetic Spin Textures in Fe3-xCoxGeTe2 Compositions using 4D-STEM

Mr. Aidan Horne[1], Dr. Daniel Mayoh[1], Dr. Damien McGrouther[2], Prof. Geetha Balakrishnan[1], Dr. Peng Wang[1]
[1]Department of Physics, University of Warwick, Coventry, United Kingdom, [2]JEOL (UK) Ltd., Welwyn Garden City, United Kingdom

173 Mean inner potential variation with strain in III-nitrides studied by off-axis electron holography

Lou Denaix[1], Dr Jing Li[1], Dr Benoît Scklenard[1], Dr David Cooper[1], Dr Eva Monroy[2]
[1]Univ. Grenoble Alpes, CEA, Leti, F-38000 Grenoble, France, [2]Univ. Grenoble Alpes, CEA, Grenoble INP, IRIG, PHELIQS, F-38000 Grenoble, France

174 Micro LED performance - a cathodoluminescence study

Mrs Névine Rochat[1], Palmerina González-Izquierdo[1], Davide Zoccarato[1], Fabian Rol[1], Julia Simon[1], Patrick Le Maitre[1], Marion Volpert[1], Matthew Charles[1], Matthieu Lafossas[1], Simona Torrengo[1], Noemie Bonnet[2], Toon Coenen[2], Lukasz Borowik[1]
[1]Univ. Grenoble Alpes, CEA, Leti, Grenoble, France, [2]DELMIC B.V, Delft, The netherlands

175 Nano-chemical Imaging and Spectroscopy at the Single-molecule Level

Mr. Francesco Simone Ruggeri[1]
[1]Wageningen University and Research, Wageningen, Netherlands

176 The Environmental Impact of Large Scientific Infrastructure

Patrick Mcbean[1,2], Jonathan JP Peters[1,2], Stephen Dooley[1], Lewys Jones[1,2]
[1]School of Physics, Trinity College Dublin, Dublin, Ireland, [2]Advanced Microscopy Lab, CRANN, Dublin, Ireland

177 Phase detection limits in electron holography with automatic stabilisation and direct electron detection

Dr Martin Hytch[1], Dr Cécile Marcelot[1], Dr Christophe Gatel[1,2]
[1]CEMES-CNRS, Toulouse, France, [2]University of Toulouse III, Toulouse, France

178 Combining SIMS elemental mapping with FIB-based imaging for multimodal analysis of biological specimen

Dr. Antje Biesemeier[1], Mr. Olivier de Castro[1], Miss Tatjana Taubitz[1,2], Miss Zahraa Berro[1,3], Mr Jean-Nicolas Audinot[1], Mr Tom Wirtz[1]
[1]Advanced Instrumentation for Nano-Analytics, Materials Research and Technology Department, Luxembourg Institute of Science and Technology, Belvaux, Luxembourg, [2]Department of Structural Biochemistry, Max Planck Institute of Molecular Physiology, Dortmund, Germany, [3]Doctoral Programme in Systems and Molecular Biomedicine of the DSSE, University of Luxembourg, Belval Esch-sur-Alzette, Luxembourg

179 Multimodal and multidimensional EELS and EDX for investigations of catalysts at the nanoscale

Dr Maria Meledina[1], Mr Dileep Krishnan[1], Mr Daen Jannis[2], Mr Maarten Wirix[1], Mr Xiaochao Wu[3], Mr Ulrich Simon[3], Mr Sorin Lazar[1], Mr Peter Tiemeijer[1], Mr Paolo Longo[1]
[1]Thermo Fisher Scientific, Eindhoven, Netherlands, [2]EMAT, University of Antwerp, Antwerp, Belgium, [3]Institute of Inorganic Chemistry, RWTH Aachen University, Aachen, Germany

180 Development of a pixelated STEM-in-SEM detector for microstructural features characterization

Julien Aubourg[1,2], Mr. Emmanuel Bouzy[2,3], Mr. Antoine Guitton[2,3], Mr. Jean-Jacques Fundenberger[2,3], Mrs. Yudong Zhang[2,3], Mr. Julien Guyon[2,3], Mr. Luc Morhain[2,3]
[1]JEOL (Europe) SAS, 1 All. de Giverny, 78290 Croissy, France, [2]Laboratoire d'Etude des Microstructures et de Mécanique des Matériaux (LEM3), Université de Lorraine, CNRS UMR 7239, Arts et Métiers, F-57070 Metz, France, [3]Laboratory of Excellence on Design of Alloy Metals for low-mAss Structures (DAMAS), University of Lorraine, 57073 Metz, France

181 Measuring the Interpretability of High-Resolution Transmission Electron Microscopy Images
William Bang Lomholdt[1], Matthew Helmi Leth Larsen[2], Cuauhtémoc Núñez Valencia[2], Jakob Schiøtz[2], Professor Thomas Willum Hansen[2]
[1]Nanolab, Technical University of Denmark, Kgs. Lyngby, Denmark, [2]Department of Physics, Technical University of Denmark, Kgs. Lyngby, Denmark
182 A new EELS spectrometer, integrated with the microscope's optics
Dr. Peter Tiemeijer[1], Mr. Terry Dennemans[1], Mr. Sander Henstra[1], Mr. Dileep Krishnan[1], Mr. Sorin Lazar[1], Mr. Paolo Longo[1], Mrs. Maria Meledina[1], Mr. Sjaak Thomassen[1], Mr. Wouter Verhoeven[1]
[1]Thermo Fisher Scientific, Eindhoven, The Netherlands
183 Materials characterization of recycled batteries (black mass): automated quantitative phase classification in 3D
Ria Mitchell[1], Mr Andy Holwell[1], Dr Richard Taylor[1], Dr Eddy Hill[1]
[1]Carl Zeiss Microscopy Ltd, Cambourne, UK
184 Multi-scale characterization of vitamin B2 (riboflavin) supplements using X-ray Microscopy, SEM, and automated phase analyses
Ria Mitchell[1], Dr Darragh Murnane[2], Mr Andy Holwell[1]
[1]Carl Zeiss Microscopy Ltd, Cambourne, UK, [2]University of Hertfordshire, Hatfield, UK
185 New paradigm for ultra-low-dose high-resolution imaging through a dedicated event-driven analytical ptychography methodology
Dr. Hoelen L. Lalandec-Robert[1,2], Prof. Dr. Jo Verbeeck[1,2]
[1]Electron Microscopy for Materials Science (EMAT), University of Antwerp , Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium
186 Cryo–electron microscopy unveils the gating mechanism of the human Kir2.1 channel
Catherine Venien-Bryan[1], Dr Carlos Fernandes[1], Dr Dania Zuniga[1], Mr Andreas Zoumpoulakis[1], Mr Rafael Veloso[1], Dr Renaud Wagner[2]
[1]IMPMC, UMR7590 Sorbonne University,CNRS,MNHN, Paris, France, [2]IMPReSs Facility, UMR 7242, CNRS University of Strasbourg, Strasbourg, France
187 Combining in-situ synchrotron and electron microscopy techniques to study NiFe catalysts for CO2 methanation
Dr Manfred Erwin Schuster[1], Dr Pilar Ferrer[2], Dr Rosa Arrigo[3]
[1]Johnson Matthey, Sonning Common, United Kingdom, [2]Diamond Light Source, Didcot, United Kingdom, [3]University of Salford, Manchester , United Kingdom
188 Correlative multi-spectroscopic and microscopic analyses for investigation of UV-C QDs bimodal emission
Dr. Adeline Grenier[1], Dr. Jesus Canaz[2], Mrs Névine Rochat[1], Dr. Zineb Saghi[1], Dr. Jean-Luc Rouvière[3], Dr. Edith Bellet-Almaric[2], Mrs. Audrey Jannaud[1], Dr. Anjali Harikumar[2], Dr. Catherine Bougerol[4], Dr. Lorenzo Rigutti[5], Dr. Eva Monroy[2]
[1]Univ. Grenoble Alpes, CEA, Leti, F-38000 Grenoble, Grenoble, France, [2]Univ. Grenoble-Alpes, CEA, Grenoble INP, IRIG, PHELIQS, 38000 Grenoble, France,, Grenoble, France, [3]Univ. Grenoble Alpes, CEA, IRIG, MEM, 38000 Grenoble, France, grenoble, France, [4]Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Neel, 38000 Grenoble, France, Grenoble, France, [5]UNIROUEN, CNRS, Groupe de Physique des Matériaux, Normandie Université, 76000 Rouen,France, Grenoble, France
189 Identifying transient defects in exsolution of nanoparticles by semi-quantitative ABF STEM imaging
Andreas Rosnes[1,3], Mr. Holger von Wenchstern[1,3,4], Mr. Jonathan Polfus[2,3], Mr. Øystein Prytz[1,3]
[1]Department of Physics, University of Oslo, Oslo, Norway, [2]Department of Chemistry, University of Oslo, Oslo, Norway, [3]Center for Material Science and Nanotechnology, University of Oslo, Oslo, Norway, [4]Felix-Bloch-Institut, Universität Leipzig, Leipzig, Germany

190 Investigation of the long-range sources of contrast in momentum-resolved STEM
Dr. Hoelen L. Lalandec-Robert[1,2], Hubert Dulisch[3,4], Prof. Dr. Rafal E. Dunin-Borkowski[5,3], Prof. Dr. Knut Müller-Caspary[6,5], Prof. Dr. Jo Verbeeck[1,2]
[1]Electron Microscopy for Materials Science (EMAT), University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [3]2nd Institute of Physics, RWTH Aachen University, Aachen, Germany, [4]Peter Grünberg Institute (PGI), Forschungszentrum Jülich, Jülich, Germany, [5]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons (ER-C), Forschungszentrum Jülich, Jülich, Germany, [6]Department of Chemistry, Ludwig-Maximilians-Universität München, München, Germany
191 Advances in characterization of nanostructured ceramic materials by means of Scanning Electron Diffraction Tomography
Sara Passuti[1], Emmanuel Guilmeau[1], Brendan Clarke[2], Dirk van der Wal[2], Philippe Boullay[1]
[1]Normandie Université, ENSICAEN, UNICAEN, CNRS, CRISMAT, Caen, France, [2]TESCAN GROUP, Libušina třída 21, Brno, Czech Republic
192 TEM Exploration of High-Performance Non-Noble Metal Catalysts for OER
David Llorens Rauret[1], Mr. Ranit Ram[2], Dr. F. Pelayo García de Arquer[2], Dr. Alba Garzón Manjón[1], Prof. Jordi Arbiol[1,3]
[1]ICN2, CSIC and BIST, Bellaterra (Barcelona), Spain, [2]ICFO and BIST, Castelldefels (Barcelona), Spain, [3]ICREA, Barcelona (Barcelona), Spain
193 Nanoscale arrangement of the healthy dentin and comparison with the dentino-genesis imperfecta-affected dentin
Dr Maxime Vallet[1,2], Dr Margot Riou[3], Mme Margot Leclercq[1], Dr Elsa Vennat[1]
[1]Université Paris-Saclay, CentraleSupélec, ENS Paris-Saclay, CNRS, LMPS, Gif-sur-Yvette, France , [2]Université Paris-Saclay, CentraleSupélec, CNRS, SPMS, Gif-sur-Yvette, France, [3]Universite de Paris, Dental Faculty, Paris, France
194 Exploring cardiac innervation by 3D light sheet imaging in horses with atrial fibrillation
Mélodie Schneider[1], PhD Sarah Dalgas Nissen[1], DVM Simon Libak Haugaard[1], Prof Rikke Buhl[1], PhD Urmas Roostalu[2]
[1]University of Copenhagen, Copenhagen, Denmark, [2]Gubra, Hørsholm, Denmark
195 Operando structural and chemical imaging of lithium battery interfaces
Sayantan Sharma[1,2], Dr. Luca Cressa[1], Dr. Tom Wirtz[1], Dr. Santhana Eswara[1]
[1]Advanced Instrumentation for Nano-Analytics (AINA), Materials Research and Technology Department, Luxembourg Institute of Science and Technology (LIST), Belvaux, Luxembourg, [2]University of Luxembourg, Belval, Luxembourg
196 High Spatio-Temporal Resolution Differential Phase Contrast Imaging via Detector Signal Digitisation
Julie Marie Bekkevold[1,2], Dr. Jonathan J. P. Peters[1,2], Prof. Ryo Ishikawa[3], Prof. Lewys Jones[1,2]
[1]School of Physics, Trinity College Dublin, Dublin, Ireland, [2]Advanced Microscopy Laboratory, Dublin, Ireland, [3]University of Tokyo, Bunkyo, Tokyo, Japan
197 Visualising microstructural dynamics of titanium aluminium nitride coatings under variable-temperature oxidation
Dr Ofentse Makgae[1], Dr Filip Lenrick[2], Dr Volodymyr Bushlya[2], Dr Jon Andersson[3], Dr Rachid M'Saoubi[3], Martin Ek[1]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]Division of Production and Materials Engineering, Lund University, Lund, Sweden, [3]R&D Materials and Technology Development, Seco Tools AB, Fagersta, Sweden
198 Advanced EELS spectroscopy characterization of AlGaN/GaN materials
Mr Esteve Drouillas[1,2], Mrs. Bénédicte Warot-Fonrose[2], Mr. Jean-Gabriel Mattei[1]

[1]STMicroelectronics Crolles 2, Crolles, FRANCE, [2]CEMES-CNRS, Toulouse, FRANCE

199 Surface facet-dependent redox dynamics in vanadium-oxide-based catalysts

Martin Ek[1], Dr. Anita Godiksen[2], Dr. Logi Arnarson[2], Dr. Poul Georg Moses[2], Dr. Søren Ramsussen[2], Prof. Magnus Skoglundh[3], Prof. Eva Olsson[3], Prof. Stig Helveg[4]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]Topsoe A/S, Kgs. Lyngby, Denmark, [3]Competence Centre for Catalysis, Chalmers University of Technology, Gothenburg, Sweden, [4]VISION, Technical University of Denmark, Kgs. Lyngby, Denmark

200 TEM Methodologies for Analyzing Thin Film Polymer Structure and Polymorphism Elucidation

Dr. Idan Biran[1], Mr. Lior Snarski[1], Mr. Sakunta Nandi[2,3], Ms. Anastasiya Sedova[1], Mr. Haim Weissman[1], Mr. Iddo Pinkas[4], Ms. Anna Eden-Kossoy[4], Mr. Sidney R Cohen[4], Mr. Tomer Lewi[2,3], Mr. Lothar Houben[4], Mr. Boris Rybtchinski[1]
[1]Department of Molecular Chemistry and Materials Science, Weizmann Institute of Science, Rehovot, Israel, [2]Faculty of Engineering, Bar-Ilan University, Ramat Gan , Israel, [3]Institute of Nanotechnology and Advanced Materials, Bar-Ilan University, Ramat Gan , Israel, [4]Department of Chemical Research Support, Weizmann Institute of Science, Rehovot, Israel

201 Three-dimensional classification of dislocations from single projections

Dr. Tore Niermann[1], Ms. Laura Niermann[1], Mr. Michael Lehmann[1]
[1]Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany

202 Microstructural evolution of zeolitic nanocrystals for CO2 capture by Environmental in-situ TEM

Dr. Simona Moldovan[1], Mr Edwin Clathworthy[2], Mrs. Kalthoum Nakouri[3], Mrs. Svetlana Mintova[2]
[1]CNRS, Rouen University, Groupe de Physique des Materiaux, Rouen, France, [2]Normandie University, ENSICAEN, Laboratoire de Catalyse et Spectrochimie, Caen, France, [3]TOTALEnergies, Solaize, France

203 Unsupervised Deep Learning approach for image registration in Correlative Microscopy for the localization of Nanoparticles

Daksh Daksh[1], Dr. Anke Kaltbeitzel[1], Mr. Gunnar Glaßer[1], Dr. Ingo Lieberwirth[1], Prof. Dr. Katharina Landfester[1]
[1]Max Planck Institute for Polymer Research, Mainz, Germany

204 Distortions correction in HR-(S)TEM and low resolution TEM images: absolute size, strain and polarization measurements

Dr. Nikolay Cherkashin[1], Mrs Sylvie Schamm-Chardon[1]
[1]CEMES-CNRS, Toulouse, France

205 Correlative TEM and APT studies of metallic Mg specimens prepared and analyzed under controlled environments

Cecile Bonifacio[1], Daniel Perea[2], Pawel Nowakowski[1], Mary Louise Ray[1], Paul Fischione[1]
[1]E.A. Fischione Instruments Inc., Export, USA, [2]Pacific Northwest National Laboratory, Richland, USA

206 Determination of 3D strain fields from dynamical diffraction effects

Dr. Laura Niermann[1], Mr. Tore Niermann[1], Mr. Michael Lehmann[1]
[1]Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany

207 Paleopalynology of Holocene birch hybridization in Iceland

Kesara Anamthawat-Jonsson[1]
[1]Institute of Life and Environmental Sciences, University of Iceland, Reykjavik, Iceland

208 Imaging MEMS motion at nano scale by time-resolved scanning electron microscopy

Mohamed Zaghloul[1,2], Abbas Kosari Mehr[1,2], Riccardo Bertacco[1,3], Simone Cuccurullo, Federico Maspero[1], Giulia Pavese[4], Hao Chen[1,2], Aldo Ghisi[4], Alberto Corigliano[4], Silvia M. Pietralunga[2,5], Alberto Tagliaferri[1,2]
[1]Dipartimento di Fisica, Politecnico di Milano, Milano, Italy, [2]CNST@PoliMi, Istituto Italiano di Tecnologia (IIT), Milano, Italy, [3]Polifab, Politecnico di Milano, Milano, Italy, [4]Dipartimento di

Ingegneria Civile e Ambientale, Politecnico di Milano, Milano, Italy, [5]Institute for Photonics and Nanotechnologies (IFN)—National Research Council (CNR), Milano, Italy

209 Fine structure tuning for strongly correlated functionalities in high entropy oxides

Dr. Di Wang[1,2], Mr. Abhishek Sarkar[1,3], Mr. Gleb Iankevich[1,4], Mr. Zhibo Zhao[1], Mr. Horst Hahn[1,3,4], Mr. Robert Kruk[1], Mr. Christian Kuebel[1,2]

[1]Karlsruhe Institute of Technology, Institute of Nanotechnology, Karlsruhe, Germany, [2]Karlsruhe Institute of Technology, Karlsruhe Nano Micro Facility (KNMFi), Karlsruhe, Germany, [3]KIT-TUD Joint Research Laboratory Nanomaterials – Technical University of Darmstadt, Darmstadt, Germany, [4]Karlsruhe Institute of Technology, Institute for Quantum Materials and Technologies, Karlsruhe, Germany

210 A crystallographic aspect of Li metal anodes: Understanding the functionality of lithium-ion all-solid-state batteries

Dr Pawel Nowakowski[1], PhD Cecile Bonifacio[1], Mrs Mary Ray[1], Mr Paul Fischione[1]

[1]Fischione Instruments, Export, USA

211 Dose fractionation and alternative scanning strategies for beam damage mitigation in event-driven 4D-STEM

Arno Annys[1,2], Dr. Hoelen Robert[1,2], Mr. Matthias Quintelier[1,2], Prof. Joke Hadermann[1,2], Prof. Jo Verbeeck[1,2]

[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium

212 Electron microscopy characterization of king scallop (Pecten maximus) shells from low-voltage SEM to 3D-EBSD reconstruction

Dr Lise Guichaoua[1], Dr Benazir Khurshid[3], M Arnaud Benchetrite[3], Ms Stéphanie Bessette[1], Dr Bryce Stewart[2], Pr Natalie Reznikov[3], Pr Roland Kröger[4], Pr Raynald Gauvin[1]

[1]McGill Electron Microscopy Research Group, Department of Mining and Materials Engineering, McGill University , Montreal, Canada, [2]Marine Biological Association, Plymouth, United Kingdom, [3]Department of Bioengineering, Faculty of Engineering, McGill University, Montreal, Canada, [4]School of Physics, Engineering and Technology, University of York, York, United Kingdom

213 Visualizing single-atom promotion of ultra-deep hydrodesulfurization catalysts (Pt-Co-Mo-S)

Principal Scientist Lars Pilsgaard Hansen[1], Mr. Christian F. Weise[1], Mrs. Hanne Falsig[1], Mr. Poul G. Moses[1], Mr. Stig Helveg[2], Mr. Michael Brorson[1]

[1]Topsoe A/S, DK-2800 Kgs. Lyngby, Denmark, [2]Center for Visualizing Catalytic Processes (VISION) Department of Physics Technical University of Denmark, DK-2800 Kgs. Lyngby, Denmark

214 Strain mapping using high-resolution electron backscatter diffraction technique: The influence of sample preparation

Dr Pawel Nowakowski[1], Mrs Mary Ray[1], Mr Paul Fischione[1]

[1]Fischione Instruments, Export, USA

216 Developing a high-temperature solid state electrochemical lab in the TEM

Mr. Søren Bredmose Simonsen[1], Mr. Zhongtao Ma[1], Mr. Kristian Speranza Mølhave[2], Mr. Christodoulos Chatzichristodoulou[1]

[1]DTU Energy, Kgs. Lyngby, Denmark, [2]DTU Nanolab, Kgs. Lyngby, Denmark

217 In situ observation of dislocation evolution in cerium oxides nanocubes in an environmental TEM

Dr Lucile Joly-Pottuz[1], Dr Rongrong Zhang[1], Dr Thierry Epicier[2], Dr Gaetan Laurens[3], Dr Tristan Albaret[3], Pr Karine Masenelli-Varlot[1]

[1]MATEIS - INSA, , France, [2]IRCELYON - UCBL, , France, [3]ILM - UCBL, , France

218 Deformation mechanisms of inorganic fullerenes used as lubrication additives: an in situ TEM nanocompression study

Dr Sankar RK Pattamadai Sundaram[1], Dr Lucile Joly-Pottuz[1], Dr Pavel Afanasiev[2], Miss Marina Benmansour[3], Pr Fabrice Dassenoy[3], Pr Karine Masenelli-Varlot[1]
[1]MATEIS - INSA Lyon, Villeurbanne, France, [2]IRCELYON - UCBL, Villeurbanne, France, [3]LTDS - ECL, Ecully, France

219 Thermo Scientific Smart EPU Software: Towards autonomous screening

Mr. Fanis Grollios[2], Mr. Holger Kohr, Julio Ortiz[1], Mr. Edward Pryor[3]
[1]Thermo Fisher Scientific, Materials & Structural Analysis, Dreieich, Germany, [2]Thermo Fisher Scientific, Materials & Structural Analysis, Eindhoven, The Netherlands, [3]Thermo Fisher Scientific, Materials & Structural Analysis, Hillboro, USA

220 Scanning transmission electron microscopy of quantum centers in diamond

Diana Propst[1], Dr. Harriet Åhlgren[2,1], Prof. Jani Kotakoski[1]
[1]University of Vienna, Faculty of Physics, , Austria, [2]University of Helsinki, Department of Physics, Helsinki, Finland

221 Unsupervised learning assisted secondary electron hyperspectral imaging for high-throughput cheminformatics analysis of materials

Jingqiong Zhang[1], James Nohl[2], Nicholas Farr[3], Cornelia Rodenburg[3], Lyudmila Mihaylova[1]
[1]Department of Automatic Control and Systems Engineering, The University of Sheffield, Sheffield, UK, [2]Department of Materials Science and Engineering, The Faraday Institution, The University of Sheffield, Sheffield, UK, [3]Department of Materials Science and Engineering, The University of Sheffield, Sheffield, UK

222 In-situ observation of rheotaxy: 2D materials‘ growth on liquid substrates

Ms Kristyna Bukvisova[2,4], Mr Radek Kalousek[1,2], Mr Marek Patocka[2], Mr Suneel Kodambaka[3], Mr Libor Novak[4], Mr Tomas Sikola[1,2], Mr. Miroslav Kolibal[1,2]
[1]CEITEC, Brno University of Technology, Brno, Czech Republic, [2]Institute of Physical Engineering, Brno University of Technology, Brno, Czech Republic, [3]Virginia Polytechnic Institute and State University, Blacksburg, United States, [4]Thermo Fisher Scientific, Brno, Czech Republic

223 SARS-CoV-2 and HCV infection and antiviral treatment monitored by multimodal imaging

PhD Ana Joaquina Perez-berna[1], Mr Kevin Mamprin[1], Miss Victoria Castro[2], Miss Gema Calvo[2], Mr Ricardo Valcárcel[1], Miss Eva Pereiro[1], Mr Pablo Gastaminza[2]
[1]ALBA Synchrotron, Cerdanyola del Vallès, Barcelona, Spain, [2]Centro Nacional de Biotecnología (CNB-CSIC) , Madrid, Spain

224 Effect of the Applied Chemical Potential on Strong Metal-Support Interaction in Ni-TiO2 Catalysts

Min Tang[1], Matteo Monai[2], Angela Melcherts[2], Kellie Jenkinson[1], Bert Weckhuysen[2], Sara Bals[1]
[1]EMAT and NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [2]Inorganic Chemistry and Catalysis group, Institute for Sustainable and Circular Chemistry and Debye Institute for Nanomaterials Science, Utrecht University, Utrecht, Netherlands

225 In situ STEM investigations of defect induced memristive switching in off-stoichiometric SrTiO3

Changming Liu[1], Alexander Meledin[2], Peng-Han Lu[3], Wahib Aggoune[4], Mohamed Abdeldayem[1], Thilo Remmele[1], Tobias Schulz[1], Kaman Yip[2], Andreas Fiedler[1], Jutta Schwarzkopf[1], Rafal Dunin-Borkowski[3], Matthias Scheffler[4], Martin Albrecht[1], Dan Zhou[1]

234 RUDDLESDEN-POPPER PLANAR DEFECTS IN METAL HALIDE PEROVSKITES: MECHANISMS OF FORMATION AND CONSEQUENCES FOR PHASE STABILITY

Irina Skvortsova[1], Mr. Tom Braeckevelt[2], Miss Nadine Schrenker[1], Mrs. Annick De Backer[1], Mr. Bapi Pradhan[3], Mr. Johan Hofkens[3], Mrs. Veronique Van Speybroeck[2], Mrs. Sandra Van Aert[1], Mrs. Sara Bals[1]

[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]CMM, Ghent University, Ghent, Belgium , [3]Photomat, KU Leuven, Leuven, Belgium

235 Continuous EELS spectrum imaging of nano-droplet crystallization heterogeneity

Ben Miller[1], Cory Czarnik[1]
[1]Gatan, Inc., Pleasanton, USA

236 Electron Channeling Contrast Imaging (ECCI) of Ion Battery Cathode Materials

Ph.d. Candidate Meysam Naghizadeh[1], Dr. Chisu Kim[2], Pr. Raynald Gauvin[1]
[1]Department of Mining and Materials Engineering, McGill University, Montréal, Canada, [2]Center of Excellence in Transportation Electrification and Energy Storage Hydro Québec, Varennes, Canada

237 Application of reinforcement learning to aid the alignment of an electron microscope

Richard Konstantin Jinschek[1], Dr. Mounib Bahri[2], Dr. Mario Gianni[3], Dr. Yao-Chun Shen[4], Dr. Nigel D. Browning[2,5]
[1]Distributed Algorithms Centre for Doctoral Training, University of Liverpool, Liverpool, UK, [2]Department of Mechanical, Materials and Aerospace Engineering, University of Liverpool, Liverpool, UK, [3]Department of Computer Science, University of Liverpool, Liverpool, UK, [4]Department of Electrical Engineering and Electronics, University of Liverpool, Liverpool, UK, [5]SenseAI Innovations Ltd., Brodie Tower, University of Liverpool, Liverpool, UK

238 Progress in 3D phase-contrast imaging using 4D-STEM: increased dose-efficiency and depth of field

Philipp Pelz[1,2], Dr. Andrey Romanov[1,2], Dr. Shengbo You[1,2], Dr. Mary Scott[3,4], Dr Colin Ophus[4], Dr Min Gee Cho[3,4], Daniel Stroppa[5], Mingjian Wu[1]
[1]Department of Materials Science & Engineering, FAU Erlangen-Nürnberg, Erlangen, Germany, [2]Institute of Micro- and Nanostructure Research (IMN) \& Center for Nanoanalysis and Electron Microscopy (CENEM), Erlangen, Germany, [3]Department of Materials Science and Engineering, University of California Berkeley, Berkeley, United States, [4]The Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, United States, [5]DECTRIS AG, Baden, Switzerland

239 Cation Vacancies Regulate the Electron Spin Configuration of Cathode Catalytic Additives towards Robust Li-S Batteries

PhD JING YU[1,2], Mr. Andreu Cabot[2], Mr. Jordi Arbiol[1]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), Bellaterra, 08193, Spain, [2]Catalonia Institute for Energy Research（IREC）, Sant Adrià de Besòs, 08930 , Spain

240 Vacancy-driven electron spin engineering to promote Li-S redox reactions

PhD JING YU[1,2], Mr. Andreu Cabot[2], Mr. Jordi Arbiol[1]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), Bellaterra, 08193, Spain, [2]Catalonia Institute for Energy Research (IREC), Sant Adrià de Besòs, 08930 , Spain

241 Information Transfer Improvement by Parallax Correction and Ptychography Reconstruction Applied to Large-Area 4D STEM Experiments

Daniel Stroppa[1], Dr. Stephanie Ribet[2], Dr. Georgios Varnavides[2], Dr. Colin Ophus[2], Dr. Philipp Pelz[3]
[1]DECTRIS, Baden-Daettwil, Switzerland, [2]NCEM, Molecular Foundry, Lawrence Berkeley National Laboratory,, Berkeley, USA, [3]Institute of Micro- and Nanostructure Research (IMN) & Center for Nanoanalysis and Electron Microscopy, Erlangen, Germany

242 Contrast Optimization Aided by Machine Learning Applied to Virtual 4D-STEM Images

Daniel Stroppa[1], Dr. Roberto dos Reis[2,3,4]
[1]DECTRIS, Baden-Daettwil, Switzerland, [2]Department of Materials Science and Engineering, Northwestern University, Evanston, USA, [3]Northwestern University Atomic and Nanoscale Characterization Experimental (NUANCE) Center, Evanston, USA, [4]International Institute for Nanotechnology, Northwestern University, Evanston, USA

243 Scanning Transmission Election Microscopy Observations of Twisted Epitaxial Molybdenum Disulfide-Gold-Molybdenum Disulfide Heterostructures
Yi Cui[1], Prof. Robert Sinclair[1]
[1]Department of Materials Science and Engineering, Stanford University, Stanford, United States
244 Deep Learning-Assisted Multivariate Analysis for Nanoscale Characterization of Heterogeneous Beam-Sensitive Materials
Fanzhi Su[1], Dr Felix Utama Kosasih[1], Dr Tian Du[2], Dr Sinclair Ryley Ratnasingham[2], Prof Joe Briscoe[2], Prod Caterina Ducati[1]
[1]Department of Materials Science and Metallurgy, University of Cambridge, Cambridge , UK, [2]Department of Materials Science and Metallurgy, University of Cambridge, Cambridge , UK, [3]School of Engineering and Materials Science and Materials Research Institute, Queen Mary University of London, London, UK, [4]Department of Materials and Centre for Processable Electronics, Molecular Science Research Hub, Imperial College London, London, UK
245 Investigating All-Inorganic Halide Perovskite Phase Transformations via in-situ 4D STEM Heating Experiments
Mr Tom Warwick[1], Mr. Paul Smeets[2,3], Mr. Roberto dos Reis[2,3]
[1]Gatan, Inc., Pleasanton, United States, [2]Department of Materials Science and Engineering, Northwestern University, Evanston, United States, [3]Northwestern University Atomic and Nanoscale Characterization Experimental (NUANCE) Center, Northwestern University, Evanston, United States
246 Depth sensitivity of atomic resolution secondary electron imaging
Professor Koh Saitoh[1], Hirokazu Tamaki[1]
[1]Institute of Materials and Systems for Sustainability, Nagoya University, Nagoya, Japan, [2]Department of Applied Physics, Nagoya University, Nagoya, Japan, [3]Hitachi High-Tech Corporation, Hitachinaka, Japan
247 Unveiling Structural Heterogeneity and Imbalance of Gold Decahedral Nanoparticles using Four-dimensional Scanning Transmission Electron Microscopy
Oliver Lin[1], Dr. Zhiheng Lyu[1], Mr. Hsu-Chih Ni[1], Ms. Yetong Jia[2], Prof. Kejie Zhao[2], Prof. Jian-Min Zuo[1], Prof. Qian Chen[1]
[1]University of Illinois, Urbana-Champaign, Urbana, USA, [2]Purdue University , West Lafayette, USA
248 Investigating multiferroic phase change dynamics using in-situ electron counted spectrum imaging with synchronized holder control
Liam Spillane[1], Dr Michele Conroy[2]
[1]Gatan Inc., Pleasanton, USA, [2]Department of Materials, London Centre of Nanotechnology, Henry Royce Institute, Imperial College London, London, UK
249 Maximizing Speed and Sensitivity: Simultaneous High-throughput EDS-WDS Elemental Mapping in the SEM
Shangshang Mu[1], David Stowe[1]
[1]Gatan/EDAX, Pleasanton , United States
250 Atomic resolution observation of zeolitic framework and captured cations using low-dose OBF STEM technique
Dr. Kousuke Ooe[1,2], Dr. Takehito Seki[3,4], Mr. Koudai Tabata[3], Dr. Kaname Yoshida[2], Prof. Atsushi Nakahira[5], Mr. Yuji Kohno[6], Prof. Yuichi Ikuhara[2,3], Prof. Naoya Shibata[2,3]
[1]Monash University, Clayton, Australia, [2]Japan Fine Ceramics Center, Nagoya, Japan, [3]The University of Tokyo, Bunkyo, Japan, [4]JST PRESTO, Kawaguchi, Japan, [5]Osaka Metropolitan University, Sakai, Japan, [6]JEOL Ltd., Akishima, Japan
251 Full-field illumination ptychography with a structured electron beam
Hirokazu Tamaki[1,2], Dr. Koh Saitoh[3]

[1]Graduate School of Engineering, Nagoya University, Nagoya, Japan, [2]Research & Development group, Hitachi Ltd., Kokubunji, Japan, [3]Institute of Materials and Systems for Sustainability, Nagoya University, Nagoya, Japan

252 Linking form and function: hyperspectral and nanostructural characterisation of photonic crystals in butterflies

Professor Peta Clode[1], Anna-Lee Jessop[2], Kyle DeMarr[3], Remi Mauxion[4], Owen McMillan[4], Nipam Patel[5], Bodo Wilts[6], Gerd Schroeder-Turk[2]
[1]University of Western Australia, Perth, Australia, [2]Murdoch University, Perth, Australia, [3]University of California, Berkeley, USA, [4]Smithsonian Tropical Research Institute, Gamboa, Panama, [5]Marine Biological Laboratory, Chicago, USA, [6]University of Salzburg, Salzburg, Austria

253 ORGANOIDS : UNVEILING INSIGHTS WITH VOLUME ELECTRON MICROSCOPY

Mr Lu Thon Beng[1], Mr Victor Racine[2], Mrs Anne Beghin[3], Dr Isabelle Guerin-Bonne[1,2,3]
[1]Electron Microscopy Unit, Yong Loo Lin School of Medicine, National University of Singapore, , Singapore, [2]Quantacell, Montpellier, France , [3]Microscopy platform SiMBA, Mechanobiology Institute, National University of Singapore, , Singapore, [4]Department of Microbiology and Immunology, Immunology Translational Research Programme, Yong Loo Lin School of Medicine, National University of Singapore, , Singapore, [5]Life Sciences Institute, Immunology Programme, National University of Singapore, , Singapore

254 Effect of the content of intermetallic compounds on creep in tin-based solders

Tianhong Gu[1,4], Mr. Yilun Xu[2,4], Mr. Ben Britton[3,4], Mr. Christopher Gourlay[4], Mr. Fionn Dunne[4]
[1]Xi'an Jiaotong-Liverpool University, Suzhou, China, [2]Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [3]University of British Columbia, Vancouver, Canada, [4]Imperial College London, London, UK

255 Investigation of electron-beam-induced charging in a dolomite needle using off-axis electron holography

Dr. Fengshan Zheng[1], Mrs Ingrid McCarroll[4], Dr Vadim Migunov[3], Dr Marco Beleggia[5], Prof Giulio Pozzi[6], Prof Julie Cairney[4], Prof Rafal Dunin-Borkowski[2]
[1]South China University of Technology, Guangzhou, China, [2]Forschungszentrum Jülich, Jülich, Germany, [3]RWTH Aachen University, Aachen, Germany, [4]The University of Sydney, Sydney, Australia, [5]Technical University of Denmark, Denmark, Denmark, [6]University of Modena and Reggio Emilia, Modena, Italy

256 OpenECCI - A Streamlined Open-Source Workflow for Electron Channelling Contrast Imaging of Crystal Defects

Zhou Xu[1], Dr. Håkon W. Ånes[2,3], Dr. Sergey Gorelick[1,4], Dr. Xiya Fang[1], Dr. Peter Miller[1]
[1]Monash Centre for Electron Microscopy, Clayton, Australia, [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway, [3]Xnovo Technology Aps, Køge, Denmark, [4]Ramaciotti Centre for Cryo-Electron Microscopy, Clayton , Australia

257 Mapping electric fields in real nanodevices by operando electron holography

Dr Christophe Gatel[1], Dr Leigeng Zhang[2], Dr Kilian Gruel[2], Dr Frédéric Lorut[3], Dr Martin Hÿtch[2]
[1]CEMES-CNRS, University Toulouse III - Paul Sabatier, Toulouse, France, [2]CEMES-CNRS, Toulouse, France, [3]STMicroelectronics, Crolles, France

258 Detection limits of electric field characterization at a p-n junction by 4D-STEM

Bruno Cesar da Silva[1], Yiran Lu[1], Alexis Wartelle[1], Eva Monroy[2], Jean-Luc Rouviere[3], David Cooper[4], Dr Martien den Hertog[1]
[1]Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 38000 Grenoble, France, Grenoble, France, [2]Univ. Grenoble-Alpes, CEA, Grenoble INP, IRIG, PHELIQS, Grenoble, France, Grenoble, France, [3]Univ. Grenoble-Alpes, CEA-IRIG, MEM, Grenoble, France, Grenoble, France, [4]CEA, LETI, MINATEC, Grenoble, France, Grenoble, France

259 Studying interface charge distribution in HfO2 and Al2O3 based nanocapacitors by operando electron holography
Dr Leifeng Zhang[1], Dr Muhammad Hamid Raza[2], Dr Kilian Gruel[1], Dr Rong Wu[2], Dr Catherine Dubourdieu[3], Dr Martin Hÿtch[1], Dr Christophe Gatel[4]
[1]CEMES-CNRS, Toulouse, France, [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany, [3]Freie Universität, Berlin, Germany, [4]CEMES-CNRS, University of Toulouse - Paul Sabatier, Toulouse, France
260 Synthesis, Characterization, and Biological Evolution Indole Molecules
Hatice Mehtap Kutlu[1], Dr. ögr. üyesi Emrah KAVAK[2], Doç. Dr. Canan VEJSELOVA SEZER[3], Prof. Dr. Arif KIVRAK[1], Prof. Dr. Hatice Mehtap KUTLU[3]

284 Investigating Impact-Induced Deformation in Cold-Sprayed Aluminum-Quasicrystals Composite Coatings

Reza Jafari[1], Dr. Mari Honkanen[2], Dr. Renato Pero[3], Dr. Turkka Salminen[2], Assoc. Prof. Heli Koivuluoto[1], Prof. Minnamari Vippola[1,2]
[1]Materials Science and Environmental Engineering, Faculty of Engineering and Natural Sciences, Tampere University, Tampere, Finland, [2]Tampere Microscopy Center, Tampere, Finland, [3]Alemnis AG, Gwatt (Thun), Switzerland

285 Fast and local determination of phases in (V1-xCrx)2O3 Mott materials

Mr Seyed-Mohammad Dolatabadi-Hamedi[1], Mr Eric Gautron[1], Mr Chris Leroux[1], Mohammed Haydoura[1], Mr Julien Tranchant[1], Mr Benoit Corraze[1], Mr Laurent Cario[1], Mr Etienne Janod[1], Seyed Mohammad Dolatabadi Hamedi[1]
[1]Nantes Université, CNRS, Institut des Matériaux de Nantes Jean Rouxel, NANTES, FRANCE

286 3D fruit microstructure characterization using micro-CT imaging and deep learning-based panoptic segmentation

Leen Van Doorselaer[1], Dr. Pieter Verboven[1], Prof. Bart Nicolaï[1,2]
[1]BIOSYST-MeBioS, Postharvest group, KU Leuven, Leuven, Belgium, [2]VCBT, Leuven, Belgium

287 STEM, PED and EELS: A powerful combination for the investigation of cathode-active-materials for batteries

Thomas Demuth[1], Dr. Michael Malaki[1], Dr. Shamail Ahmed[1], Dr. Philipp Kurzhals[2,3], Dr. Andreas Beyer[1], Prof. Dr. Jürgen Janek[2], Prof. Dr. Kerstin Volz[1]
[1]Materials Science Center (WZMW) and Department of Physics, Philipps Universität Marburg, Marburg, Germany, [2]Institute of Physical Chemistry & Center for Material Research, Justus-Liebig-University, Gießen, Germany, [3]BASF SE, New Battery Materials and Systems, Ludwigshafen, Germany

288 Quantitative comparison of HRTEM and electron ptychography

Felix Bennemann[1], Prof Peter Nellist[1], Prof Angus Kirkland[1,2]
[1]Department of Materials, University of Oxford, Oxford, United Kingdom, [2]Rosalind Franklin Institute, Harwell Science & Innovation Campus, Didcot, United Kingdom

289 Multimodal OF2i-Raman – A novel high-throughput, single particle analysis method in liquids

Dr. Harald Fitzek[1,2], Christian Neuper[1], Dr. Christian Hill[3]
[1]Graz Centre for Electron Microscopy (ZFE), Graz, Austria, [2]Institute for Electron Microscopy and Nanoanalysis (FELMI), Graz, Austria, [3]Brave Analytics GmbH, Graz, Austria

290 A Real Space Understanding of Short Range Order in Disordered Rocksalt Cathodes

Dr Emma Hedley[1], Mr Liquan Pi[2], Prof. Peter G. Bruce[2,3,4], Prof. Peter D. Nellist[2]

[1]Monash University, Melbourne, Australia, [2]University of Oxford, Oxford, United Kingdom, [3]Faraday Institution, Didcot, United Kingdom, [4]The Henry Royce Institute, Oxford, United Kingdom

291 5D-ToF-STIM Hyperspectral Imaging with a keV He+ Focused Ion Beam

Dr. Dustin Andersen[1], Michael Mousley[1], Saba Tabean[1], Radek Holeňák[2], Eleni Ntemou[2], Gerhard Hobler[3], Tom Wirtz[1], Daniel Primetzhofer[2], Santhana Eswara[1]
[1]Advanced Instrumentation for Nano-Analytics (AINA), MRT Department, Luxembourg Institute of Science and Technology (LIST), Belvaux, Luxembourg, [2]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden, [3]Institute of Solid-State Electronics, TU Wien, Vienna, Austria

292 Atomic scale evolution of Ru nanoclusters on graphitic carbon nanofibers in NH3 decomposition reaction

Dr. Yifan Chen[1], Mr Benjamin Young[1], Dr Gazimagomed Aliev[2], Dr Emerson Kohlrausch[1], Dr Andreas Weilhard[1], Mr Thomas Liddy[1], Dr Wolfgang Theis[2], Prof Graham Hutchings[3], Dr Jesum Alves Fernandes[1], Prof Andrei Khlobystov[1]
[1]School of Chemistry, University of Nottingham, Nottingham, United Kingdom, [2]Nanoscale Physics Research Laboratory, School of Physics and Astronomy, University of Birmingham, Birmingham , United Kingdom , [3]Cardiff Catalysis Institute, Translational Research Hub, Cardiff University , Cardiff , United Kingdom

293 Improving Control Signals for Interference Gating

Simon Gaebel[1,2], Hüseyin Çelik[2], Dr. Christian M. Günther[2], Dr. Tolga Wagner[3], Prof. Dr. Michael Lehmann[2]
[1]Max-Born-Institut, Berlin, Germany, [2]Technische Universität Berlin, Berlin, Germany, [3]Humboldt-Universität Berlin, Berlin, Germany

294 Anisotropic van der Waals Epitaxy and Sliding of CsPbBr3 Nanoplatelets on ReSe2

Noya Ruth Itzhak[1], Dr. Irit Goldian[2], Dr. Sidney Cohen[2], Dr. Olga Brontvein[2], Katya Rechav[2], Dr. Hagai Cohen[2], Prof. Ernesto Joselevich[1]
[1]Department of Molecular Chemistry and Materials Science, Weizmann Institute of Science, Rehovot, Israel, [2]Chemical Research Support, Weizmann Institute of Science, Rehovot, Israel

295 η-Carbides (Co, Mo, or W) Nanoparticles from Octacyanometalates Precursors-Based Network

Dr Frédéric Fossard[1], Mr. Thomas Blin[2], Mrs Armelle Girard[1,3], Mrs Nathalie Guillou[3], Mrs Laure Catala[2], Mrs Annick Loiseau[1], Mr. Vincent Huc[2]
[1]Université Paris-Saclay, ONERA, CNRS, LEM, Châtillon, France, [2]ICMMO, CNRS, Université Paris-Saclay, Orsay, France, [3]ILV, UMR CNRS 8180, UVSQ, Université Paris-Saclay, Versailles, France

296 Electron Microscopy of Novel Lithium Alloy Anodes for Solid State Batteries

Dr Ed Darnbrough[1], Mrs Myra Ng[1], Dr Sreejith Olakkil Veedu[1], Prof David Armstrong[1], Prof Chris Grovenor[1], Prof Pete Nellist[1]
[1]University of Oxford, Oxford, United Kingdom

297 Unveiling the Optoelectronic and Thermal Properties of SnSe Polycrystals via EELS

Francesco Salutari[1], Dr. Sharona Horta[2], Mr. Marc Botifoll[1], Dr. Maria Chiara Spadaro[1,3,4], Dr. Maria Ibañez[2], Dr. Jordi Arbiol[1,5]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2) , Campus UAB, Bellaterra, 08193 Barcelona, Spain, [2]Institute of Science and Technology Austria (ISTA), AM Campus 1, 3400 Klosterneuburg, Austria, [3]Department of Physics and Astronomy “Ettore Majorana”, University of Catania, via S. Sofia 64, Catania 95123, Italy, [4]CNR-IMM, via S. Sofia 64, Catania 95123, Italy, [5]ICREA, Pg Lluis Companys 23, 08010 Barcelona, Spain

298 Quantitative comparison between the diffuse scattering from three-dimensional electron diffraction and single-crystal X-ray diffraction

Romy Poppe[1], Dr. Nikolaj Roth[2], Prof. Reinhard B. Neder[3], Dr. Lukáš Palatinus[4], Prof. Bo B. Iversen[2], Prof. Joke Hadermann[1]

[1]University of Antwerp, Department of Physics , Groenenborgerlaan 171, B-2020 Antwerp, Belgium, [2]Aarhus University, Department of Chemistry , Langelandsgade 140, 8000 Aarhus, Denmark, [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Kirstallographie und Strukturphysik , Staudtstraße 3, 91058 Erlangen, Germany, [4]Czech Academy of Sciences, Department of Structure Analysis , Na Slovance 2, 182 21 Prague, Czech Republic

299 In situ electron beam irradiation of Ti3C2Tz MXenes. A STEM-EELS study

Ayoub Benmoumen[1,2], Dr. Marie-Laure David[1], Dr. Eric Gautron[2], Dr. Sophie Morisset[3], Dr. Aurélien Habrioux[3], Dr. Stéphane Célérier[3], Pr. Philippe Moreau[2], Pr. Vincent Mauchamp[1]
[1]Université de Poitiers, ISAE-ENSMA, CNRS, PPRIME, Poitiers, France, [2]Nantes Université, CNRS, IMN, Nantes, France, [3]Université de Poitiers, CNRS, IC2MP, Poitiers, France

300 In situ scanning precession electron diffraction study of chemo-mechanical interactions during Zr oxidation

Dr. Dan Zhou[2,3], Yongwen Sun[1], Dr. Ying Han[1], Dr. H. Hugo Perez Garza[3], Dr. Alejandro Gomez Perez[4], Dr. Athanassios S. Galanis[4], Dr. Stavros Nicolopoulos[4], Prof. Dr. Yang Yang[1]

303 Phonon dispersion surfaces from the electron microscope compared with calculations including dynamical diffraction

Dr. Benedikt Haas[1], Steven Quillin[2], Tracy Lovejoy[2], Niklas Dellby[2], Ondrej Krivanek[2,3], Adnan Hammud[4], Tim Schröder[1], Christoph Koch[1], Peter Rez[2]
[1]Department of Physics & Center for the Science of Materials Berlin, Humboldt-Universität zu Berlin, Berlin, Germany, [2]Bruker AXS (formerly Nion Co. R&D), Kirkland, USA, [3]Department of Physics, Arizona State University, Tempe, USA, [4]Department of Inorganic Chemistry, Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany

304 Influential factors affecting the quantification accuracy of magnetic moments with electron magnetic chiral dichroism technique

Dr Xiaoxiao Fu[1], Mr Zhixin Zeng[1], Miss Qiwen Hu[1], Dr Xiaoxu Huang[1]
[1]International Joint Laboratory for Light Alloys (MOE), College of Materials Science and Engineering, Chongqing University, Chongqing , China

305 Structure, Chemistry, and Interface of Dispersoids in Powder Metallurgically Processed Ni based 617 ODS Alloy

Chanchal Ghosh[1,3], Dr. Arup Dasgupta[1,3], Dr. Sudip Kumar Sarkar[2], Dr. Deodatta Shinde[2,3], Dr. R Mythili[1,3], Dr. Aniruddha Biswas[2,3]
[1]Metallurgy and Materials Group, Indira Gandhi Centre for Atomic Research, Kalpakkam - 603102, India, [2]Materials Science Division, Bhabha Atomic Research Centre, Trombay, Mumbai – 400085, India, [3]Homi Bhabha National Institute, Anushaktinagar, Mumbai – 400094, India

306 Mitigating radiation damage in beam sensitive battery materials by adapting scanning parameters

Mme. Hannah Nickles Jäkel[1], Mr Eric Gautron[1], Mr Maurice Peeman[2], Mr Philippe Moreau[1], Ms Patricia Abellan[1]
[1]Nantes Université, CNRS, Institut des Matériaux de Nantes Jean Rouxel, IMN, 44000 Nantes, France, [2]Thermo Fisher Scientific, Eindhoven, Netherlands

307 High-resolution 3D chemical imaging of light elements by time-of-flight mass spectrometry

Valentine Riedo-Grimaudo[1], Mr. Lex Pillatsch[1], Mr. James Whitby[1], Mr. Renato Pero[2], Mr. Nicholas Randall[2], Mr Louis Lafeuille[2], Mr. Masoud Baghernejad[3]
[1]TOFWERK AG, Thun, Switzerland, [2]Alemnis AG, Thun, Switzerland, [3]Helmholtz-Institute Münster, Forschungszentrum Jülich GmbH, Münster, Germany

308 In-situ electrical characterization of MOSFET transistors using AFM-in-SEM solution

Ondrej Novotny[1], Libor Strakos[2], Marek Patocka[1], Vojtech Schanilec[1], Veronika Hegrova[1], Umberto Celano[3], Tomas Vystavel[2], Dr. Jan Neuman[1]
[1]NenoVision s. r. o., Brno, Czech Republic, [2]Thermo Fisher Scientific, Brno, Czech Republic, [3]Arizona State University, Tempe, USA

309 Correlative imaging of the human anterior cruciate ligament by micro-CT and histology

Federica Orellana[1,2], Alberto Grassi[3], Gregorio Marchiori[3], Matteo Berni[3], Nicola Francesco Lopomo[4], Stefano Zaffagnini[3], Annapaola Parrilli[1]
[1]Empa - Center for X-ray Analytics, Dübendorf, Switzerland, [2]University of Fribourg, Fribourg, Switzerland, [3]IRCCS - Istituto Ortopedico Rizzoli, Bologna, Italy, [4]Politecnico di Milano, Milano, Italy

310 Exploring the 3D architecture of native and stained human intervertebral discs through micro-CT

Raluca-Ana-Maria Barna[1,3,4], Federica Orellana[1,2], Marie-Rosa Fasser[4,5], Daniel Valent[4], Jonas Widmer[4,5], Annapaola Parrilli[1]
[1]Empa - Center for X-Ray Analytics, Dübendorf, Switzerland, [2]University of Fribourg, Fribourg, Switzerland , [3]University of Bern, , Switzerland, [4]Balgrist University Hospital - Spine Biomechanics, Zurich, Switzerland, [5]Balgrist University Hospital - Department of Orthopedics, Zurich, Switzerland

311 Developing a multimodal imaging pipeline for molecular biochemical studies with a 3D approach

Dr Caroline Bissardon[1], Victor Armijo[1], Dr. Sylvain Bohic[2,3], Dr. Peter Cloetens[3], Dr. Matthew W. Bowler[1], Gergely Papp[1]
[1]European Molecular Biology Laboratory, Grenoble, France, [2]Inserm, UA7, Rayonnement Synchrotron pour la Recherche Biomédicale (STROBE), Grenoble, France, [3]European Synchrotron Radiation Facility, Grenoble, France

312 3D atomic-resolution imaging of nanomaterials based on exit wave reconstruction

Sophie Kargo Kaptain[1], Mr. Joakim Kryger-Baggesen[1], Mrs. Rikke Egeberg Tankard[2], Mr. Fu-Rong Chen[3], Mr. Dirk van Dyck[4], Mr. Joerg R. Jinschek[1,5], Mr. Jakob Kibsgaard[2], Mr. Christian Danvad Damsgaard[1,5], Mr. Stig Helveg[1]

325 4D STEM in SEM with a Fast Pixelated Direct Detector
Dr. Martin Huth[1], Dr. Björn Eckert[1], Dr. Petra Majewski[1], Dr. Stefan Aschauer[1], Prof. Lothar Strüder[2], Dr. Heike Soltau[1]
[1]PNDetector GmbH, Munich, Germany, [2]PNSensor GmbH, Munich, Germany
326 Identification of inorganic fibres in workplace air by SEM-EDS
Dr. Markus Mattenklott[1], Dennis Kaiser[1], Bianca Gasse[1]
[1]Institute for Occupational Safety and Health (IFA), Sankt Augustin, Deutschland
327 Automated feedback correction of the specimen drift at the atomic scale
Dr Christophe Gatel[1]
[1]CEMES-CNRS, University Toulouse III - Paul Sabatier, Toulouse, France, [2]CEMES-CNRS, Toulouse, France
328 Quantification of Dynamic Scattering Effects in Molecular Crystals using Large Angle Rocking Beam Electron Diffraction

Robert Busch[1,2], Hsu-Chih Ni[1,2], Prof. Jian-Min Zuo[1,2]
[1]University of Illinois at Urbana Champaign, Urbana, United States, [2]Materials Research Laboratory, Urbana, United States

329 Imaging Toxoplasma gondii tachyzoite infection: tracking a single protein effector by X-ray fluorescence microscopy

Dr Caroline Bissardon[1], Dr. Alexandre Boudgour[2], Victor Armijo[1], Dr Peter Cloetens[3], Gergely Papp[1], Dr Mohammed-Ali Hakimi[2], Dr Matthew W. Bowler[1]
[1]EMBL-European Molecular Biology Laboratory, Grenoble, France, [2]Institute for Advanced Biosciences (IAB), Team Host-Pathogen Interactions and Immunity to Infection, INSERM U1209, CNRS UMR5309, University Grenoble Alpes, Grenoble, France, [3]European Synchrotron Radiation Facility, Grenoble, France

330 Fully Integrated Pixelated 4D-STEM Detector for Scanning Electron Microscopes

Pavel Stejskal[1], Rastislav Motúz[2], Michal Horák[3], Tomáš Šikola[4]
[1]AdvaScope, Brno, Czech Republic, [2]TESCAN Group, Brno, Czech Republic, [3]Brno University of Technology, CEITEC, Brno, Czech Republic, [4]Brno University of Technology, Institute of Physical Engineering, Brno, Czech Republic

331 Advanced electron microscopy of trimetallic core-shell Pt/Au_xCu_{1-x} nanoparticles

Just Jonasse[1], Ms Marta Perxés i Perich[1], Ms Savannah Turner[1], Dr Jessi van der Hoeven[1]
[1]Materials Chemistry and Catalysis, Debye Institute for Nanomaterials Science, Utrecht University, Utrecht, Netherlands

332 Growth of Au-seeded GaAs-GaSb nanowires explored in environmental TEM

Phd Candidate Mikelis Marnauza[1,2], Dr. Robin Sjökvist[1,2], Ms. Azemina Kraina[1,2], Dr. Daniel Jacobsson[1,2,3], Prof. Kimberly Dick-Thelander[1,2]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]NanoLund, Lund University, Lund, Sweden, [3]National Centre for High Resolution Electron Microscopy, Lund University, Lund, Sweden, [4]Solid State Physics, Lund University, Lund, Sweden

333 Investigating the ultrafast phase transition of vanadium dioxide using time-resolved three-dimensional electron diffraction

Dr. Arthur Niedermayr[1,2], Prof. Hongyi Xu[3], Michael Yannai[2], Dr. Gaolong Cao[1], Prof. Bertina Fisher[4], Prof. Lior Kornblum[2], Prof. Ido Kaminer[2], Prof. Xiaodong Zou[3], Prof. Jonas Weissenrieder[1]
[1]Materials and Nano Physics, School of Engineering Sciences, KTH Royal Institute of Technology, Stockholm SE-100 44, Sweden, [2]Department of Electrical and Computer Engineering, Technion–Israel Institute of Technology , Haifa 32000, Israel, [3]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden, [4]Department of Physics, Technion—Israel Institute of Technology, Haifa 32000, Israel

334 Effect of preparation and oxygen evolution catalysis on CoNiFe oxide electrocatalysts revealed by STEM-EELS

Dr. Nils Rockstroh[1], Ms. Trang Pham[1], Mr. Carsten Kreyenschulte[1], Ms. Annette-Enrica Surkus[1], Mr. Robert Francke[1]
[1]Leibniz Institute for Catalysis e.V. (LIKAT), Rostock, Germany

335 L-TEM characterization of controlled skyrmion nucleation in synthetic antiferromagnetic multilayers

Sara Villa[1], Dr Christopher Barker[2], Dr Kayla Fallon[1], Mr Colin Kirkbride[1], Dr Trevor Almeida[1], Prof. Cristopher Marrows[3], Prof. Stephen McVitie[1]
[1]School of Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom, [2]National Physics Laboratory (NPL), Teddington, United Kingdom, [3]School of Physics and Astronomy, University of Leeds, Leeds, United Kingdom

336 Quantum phase modulation and retrieval in an ultrafast transmission electron microscope

Dr. Cameron Duncan[1], Beatrice Ferrari[1], Irene Ostroman[1], Maria Giulia Bravi[1], Sang Tae Park[2], Daniel Masiel[2], Jean Christophe Olaya[3], Eduardo Dias[4], Javier García de Abajo[4], Giovanni Maria Vanacore[1]

384 Electron beam imaging of extremely confined optical modes in topology-optimized dielectric photonic cavities

Dr. Michael Seifner[1,2], M.Sc. Ali Babar[2,3], B.Sc. Anne Sofie Darket[2,3], Assistant Professor Babak Vosoughi Lahijani[2,3], Associate Professor Rasmus Christiansen[2,4], Senior Researcher Elizaveta Semenova[2,3], Professor Søren Stobbe[2,3], Senior Researcher Philip Kristensen[2,3], Senior Researcher Shima Kadkhodazadeh[1,2]
[1]DTU Nanolab, Technical University of Denmark, Kongens Lyngby, Denmark, [2]NanoPhoton - Center for Nanophotonics, Technical University of Denmark, Kongens Lyngby, Denmark, [3]DTU Electro, Technical University of Denmark, Kongens Lyngby, Denmark, [4]DTU Construct, Technical University of Denmark, Kongens Lyngby, Denmark

385 Unveiling Atomic-Scale Defects and Optical
Properties within Quasi_2D Perovskite single crystals

Xinjuan Li[1]
[1]University of Cambridge, Cambridge, United Kingdom

386 Modification of topological phenomena at hybrid Bi2Se3/organic interfaces

Miss Mairi McCauley[1], Dr. Timothy Moorsom[2], Professor. Quentin Ramasse[3], Dr. Craig Knox[4], Dr. Matthew Rogers[4], Professor. Donald MacLaren[1]
[1]SUPA, School of Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom, [2]School of Chemical and Process Engineering, University of Leeds, Leeds, United Kingdom, [3]SuperSTEM Laboratory, SciTech Daresbury Campus, Daresbury, United Kingdom, [4]School of Physics and Astronomy, University of Leeds, Leeds, United Kingdom

387 AI Automation for Transmission Electron Microscope Alignment

Loïc Grossetête[1], Cécile Marcelot[3], Christophe Gatel[1], Sylvain Pauchet[2], Martin Hytch[1]
[1]I3EM, CEMES-CNRS, Toulouse, France, [2]LII, Fédération ENAC ISAE-SUPAERO ONERA, Université de Toulouse, Toulouse, France, [3]Plat. Structures et Propriétés, CEMES-CNRS, Toulouse, France

388 Correlating absorption and diffraction contrast tomography on earth and space materials

Olivia Barbee[1], Jette Oddershede[1], Matthew Pankhurst[2], Florian Bachmann[1], Stephen Hall[3], Jonas Engqvist[3], Rhian Jones[4], Anders Svensson[5], Erik Lauridsen[1], Jun Sun[1]
[1]Xnovo Technology ApS, Køge, Denmark, [2]ITER/INVOLCAN, Tenerife, Spain, [3]Lund University, Lund, Sweden, [4]The University of Manchester, Manchester, UK, [5]University of Copenhagen, Copenhagen, Denmark

389 Effect of electron microscopy sample preparation protocol on the preservation of liposomes in cell culture

Associate Professor Paul Kempen[1], Nikoline Lykke Faurschou[1], Jonas Rosager Henriksen[2], Andrew urquhart[2]
[1]DTU Nanolab, Technical University of Denmark, Kgs. Lyngby, Denmark, [2]DTU Health Tech, Technical University of Denmark, Kgs. Lyngby, Denmark

390 Thermal vibrations in inverse dynamical electron scattering

Ziria Herdegen[1], Dr. Benedikt Diederichs[2], Prof. Dr. Knut Müller-Caspary[1]
[1]Depart. Chemistry, Ludwig-Maximilians-Universität München, Munich, Germany, [2]Institute of Biological and Medical Imaging, Helmholtz Zentrum München, Neuherberg, Germany

391 Characterization of Solid Electrolyte-free Si anodes for all-solid-state batteries (ASSBs) using Cryo-STEM

Dr. Shamail Ahmed[1], Dr. Hanyu Huo[2], Mrs. Franziska Hüppe[1], Dr. Jürgen Belz[1], Prof. Dr. Jürgen Janek[3], Prof. Dr. Kerstin Volz[1]
[1]Structure and Technology Research Laboratory, Philipps University of Marburg, Marburg, Germany, [2]The Bruce Group, University of Oxford, Oxford , United Kingdom, [3]Institute of Physical Chemistry, Justus Liebig University Giessen, Giessen, Germany

392 Direct observation of the interplay between stacking polytypes and self-intercalation in epitaxial Nb1+xSe2 films

Dr. Hongguang Wang[1], BS. Jiawei Zhang[1], Dr. Chen Shen[2], Dr. Chao Yang[1], Dr. Kathrin Küster[1], Dr. Julia Deuschle[1], Prof. Ulrich Starke[1], Prof. Hongbin Zhang[2], Dr. Masahiko Isobe[1], Dr. Dennis Huang[1], Prof. Peter A. van Aken[1], Prof. Hidenori Takagi[1,3,4]
[1]Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569, Stuttgart, Germany, [2]Department of Materials and Earth Sciences, Technical University of Darmstadt, Darmstadt, Germany, [3]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, 70569 Stuttgart, Germany, [4]Department of Physics, University of Tokyo, 113-0033 Tokyo, Japan

393 Atomic Imaging of Lattice and Electron Ordering in Tensile-Strained LaCoO3 Films

Dr. Hongguang Wang[1], Dr. Bonan Zhu[2], Prof. David O. Scanlon[2], Prof. Peter A. van Aken[1]
[1]Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569, Stuttgart, Germany, [2]Department of Chemistry, University College London, London WC1H 0AJ, United Kingdom

394 Insights into the Structural Dynamics of Cu@Ag Core-Shell Nanoparticles during CO2 Reduction

Daniel Arenas Esteban[1], Dr. Lien Pacquets[1,2], Dr. Daniel Choukroun[2], Mrs. Saskia Hoekx[1,2], Dr. Ajinkya Kadu[1,3], Mr. Jonathan Schalck[2], Dr. Nick Daems[2], Prof. Tom Breugelmans[2], Prof. Sara Bals[1]
[1]Electron Microscopy for Materials Science (EMAT) and NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [2]Applied Electrochemistry and Catalysis (ELCAT), University of Antwerp, Antwerp, Belgium, [3]Centrum Wiskunde & Informatica (CWI), Amsterdam, The Netherlands

395 A Robust Toolkit to Correlate High Dimensional Multimodal Microscopy

Mr Thomas Selby[1], Mr Cullen Chosy[1,3], Dr Simon Fairclough[2], Mr Taeheon Kang[1], Dr Terry Chien-Jen Yang[1,3], Ms Hayley Gilbert[1,4], Mr Kieran Orr[1,3], Dr Tiarnan Doherty[2], Prof Paul Midgley[2], Prof Samuel Stranks[1,3]
[1]Department of Chemical Engineering and Biotechnology, University of Cambridge, Cambridge, UK, [2]Department of Materials Science and Metallurgy, University of Cambridge, Cambridge, UK, [3]Cavendish Laboratory, University of Cambridge, Cambridge, UK, [4]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, UK

396 Molecular Microscopy by Thermo-Fisher-Scientific: FTIR-Imaging of a Tintoretto-Fresco and Raman-Imaging of the Strain-Distribution in Semiconductors

Dr. Maximilian Ries[1,2], Barbara Bravo[1], Eleonora Balliana[3], Fabian Heisinger[2], Imad Limame[2]
[1]Thermo Fisher Scientific, , Germany/Italy, [2]Technische Universität Berlin, , Germany, [3]Ca' Foscari University of Venice, , Italy

397 Assessing the Precision of Local Temperature Measurement by Plasmon Energy in In-Situ Heating Electron Microscopy

Yi-Chieh Yang[1], Luca Serafini[2], Nicolas Gauquelin[2], Johan Verbeeck[2], Joerg Jinschek[1]
[1]Nanolab, Technical University of Denmark (DTU) , Kongens Lyngby, Denmark, [2]EMAT, University of Antwerp, Antwerp, Belgium

398 Enabling discovery by in-cell structural biology

Dr Julia Mahamid[1]
[1]European Molecular Biology Laboratory, Heidelberg, Germany

399 Low-Dose 4D-STEM Investigations of the Octahedral Network Structure in Formamidinium Lead Bromide Nanocrystals

Nadine Schrenker[1,2], Mr. Tom Braeckevelt[3], Mrs. Annick De Backer[1,2], Mr. Nikolaos Livakas[4], Mr. Chu-Ping Yu[1,2], Mr. Thomas Friedrich[1,2], Mr. Daen Jannis[1,2], Mr. Armand Béché[1,2], Mr. Maarten Roeffaers[5], Mr. Johan Hofkens[6], Mr. Johan Verbeeck[1,2], Mr. Liberato Manna[4], Mrs. Veronique Van Speybroeck[3], Mrs. Sandra Van Aert[1,2], Mrs. Sara Bals[1,2]
[1]Electron Microscopy for Materials Science (EMAT), University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [3]Center for Molecular Modeling, Ghent University, , Belgium, [4]Department of Nanochemistry, Istituto Italiano di Tecnologia

(IIT), Genova, Italy, [5]cMACS, Department of Microbial and Molecular Systems, KU Leuven, Leuven, Belgium, [6]Department of Chemistry, KU Leuven, Leuven, Belgium

400 In-situ beam driven experiments by Electron time-correlation microscopy of amorphous structures

Dr. Martin Peterlechner[1], Olivia Vaerst[2], Prof. Gerhard Wilde[2]

[1]Karlsruhe Institute of Technology, Laboratory for Electron Microscopy (LEM), Karlsruhe, Germany, [2]University of Münster, Institute of Materials Physics, Muenster, Germany

401 Magnetic behavior of steel studied by in-situ Lorentz microscopy, magnetic force microscopy and micromagnetic simulations

Mari Honkanen[1], Suvi Santa-aho[2], Sami Kaappa[3], Lucio Azzari[1], Henri Lukinmaa[4,5], Jaakko Kajan[4], Samuli Savolainen[4], Mikko Palosaari[4], Lasse Laurson[3], Minnamari Vippola[1,2]

[1]Tampere Microscopy Center / Tampere University, Tampere, Finland, [2]Materials Science and Environmental Engineering / Tampere University, Tampere, Finland, [3]Computational Physics Laboratory / Tampere University, Tampere, Finland, [4]Stresstech Oy, Jyväskylä, Finland, [5]Verity, Zurich, Switzerland

402 Thapsigargin induces non-apoptotic programmed cell death in RBL-1 cells

Dr. Philip Steiner[1], Mr. Hubert Kerschbaum[2], Mrs. Ancuela Andosch[1,2], Mr. Korollus Melek[3], Mrs. Susanna Zierler[1,4]

[1]Institute of Pharmacology, Johannes Kepler University, Linz, Austria, [2]Department of Biosciences and Medical Biology, Paris Lodron University, , Austria, [3]Institute of Biochemistry and Molecular Medicine, University Bern, , Switzerland, [4]Walther Straub Institute of Pharmacology, Ludwig Maximilians University, Munich, Germany

403 Multimodal control of the magneto-structural phase transition in FeRh studied by TEM

Jan Hajducek[1], Martin Tichý[2], Jon Ander Arregi[1], Fabrizio Carbone[3], Thomas LaGrange[3], Vojtěch Uhlíř[1,2]

[1]Central European Institute of Technology (CEITEC). Brno University of Technology, Brno, Czech Republic, [2]Institute of Physical Engineering (IPE). Brno University of Technology, Brno, Czech Republic, [3]Laboratory for Ultrafast Microscopy and Electron Scattering (LUMES). École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

404 Defects and alloy ordering in Pt-Cu nanoparticulate electrocatalysts

Ana Rebeka Kamsek[1,2], Dr. Francisco Ruiz-Zepeda[1], Anja Logar[1,3], Dr. Marjan Bele[1], Prof. Dr. Goran Dražić[1], Prof. Dr. Nejc Hodnik[1,3]

[1]Department of Materials Chemistry, National Institute of Chemistry, Ljubljana, Slovenia, [2]Faculty of Chemistry and Chemical Engineering, University of Ljubljana, Ljubljana, Slovenia, [3]University of Nova Gorica, Nova Gorica, Slovenia

405 Whole-brain 3D quantification of alpha-synuclein spreading and toxicity in a mouse model of Parkinson's disease

Phd Student Frederikke Lynge Sørensen[1,2], Annika Højrup Runegaard Thomsen[1], Urmas Roostalu[1], Jacob Lercke Skytte[1], Evi Alexiou[1], Jacob Hecksher-Sørensen[1], Poul Henning Jensen[2], Yasir Gallero-Salas[1], Henrik Björk Hansen[1]

[1]Gubra Aps, Hørsholm, Denmark, [2]Biomedicine and DANDRITE, Aarhus University, Aarhus, Denmark

406 NP-SAM: Implementing the Segment Anything Model for Easy Nanoparticle Segmentation and Analysis in Electron Microscopy

Rasmus Larsen[1], Mr. Torben L. Villadsen[1], Ms. Jette K. Mathiesen[2], Ms. Kirsten M. Ø. Jensen[3], Mr. Espen D. Bøjesen[1]

Technical University of Denmark, Kongens Lyngby, Denmark, [3]Department of Chemistry, University of Copenhagen, Copenhagen, Denmark

407 Towards advanced polymer membranes for hydrogen technologies through dose-optimised Focused Ion Beams

Dr Ofentse Makgae[1], Dr Martha Briceno de Gutierrez[1]

[1]Johnson Matthey Technology Centre, Reading, United Kingdom

408 NBED investigations of coaxial (Al,In,Ga)As nanowires

Alina Friemel[1], Dr. Tore Niermann[1], Dr. Laura Niermann[1], Dr. Paul Schmiedeke[2], Dr. Gregor Koblmüller[2], Prof. Dr. Michael Lehmann[1]

[1]Technische Universität Berlin, Berlin, Germany, [2]Technische Universität München, Munic, Germany

409 Surface Polarity Dynamics and Strong Reconstruction in Partially Reduced Nickelate Films

Prof. Dr. Peter A. Van Aken[1], Mr. Chao Yang[1], Mrs. Rebecca Pons[1], Mr. Wilfried Sigle[1], Mr. Hongguang Wang[1], Mrs. Eva Benckiser[1], Mr. Gennady Logvenov[1], Mr. Bernhard Keimer[1]

[1]Max Planck Institute for Solid State Research, Stuttgart, Germany

410 Characterization of structure and mixing in nanoparticle hetero-aggregates using convolutional neural networks: 3D-reconstruction versus 2D-projection

Dr. Christoph Mahr[1], Dr. Florian Krause[1], Jakob Stahl[2], Beeke Gerken[1], Dr. Marco Schowalter[1], Dr. Tim Grieb[1], Prof. Dr.-Ing. Lutz Mädler, Prof. Dr. Andreas Rosenauer

[1]Universität Bremen, Bremen, Germany, [2]Leibniz Institut für Werkstofforientierte Technologien, Bremen, Germany

412 Investigation of metal-to-metal hydride phase transformations in magnesium thin films using STEM techniques

Dr Gopi Krishnan[1], Herman Schreuders[2], Lars Bannenberg[2], Joerg Jinschek[1]

[1]DTU Nanolab, Technical University of Denmark, Lyngby, Denmark, [2]Faculty of Applid Sciences, Delft University of Technology, Delft, The Netherlands

413 Optimizing Backscattered Electron Detection in SEM: Diode Layout and Collection Efficiency

Dr. Mozhdeh Abbasi[1], Dr. Maximilian Schmid[1], Dr. Alessia Mafodda[1], Dr. Stefan Aschauer[1]

[1]PNDetector GmbH, Munich, Germany

414 Empowering STEM in SEM: Integrative Approaches for Enhanced Detection

Dr. Maximilian Schmid[1], Mozhdeh Abbasi[1], Adam Meisel[1], Yassine Elamri[1], Dr. Alessia Mafodda, Dr. Stefan Aschauer[1]

[1]PNDetector GmbH, Munich, Germany

415 Seeking peak precision in atomic EELS mapping with counting mode direct electron detection

Dr Duncan Alexander[1], Dr Chih-Ying Hsu[1,2], Dr Pau Torruella[1], Sebastian Cozma[1], Lucia Varbaro[2], Prof. Jean-Marc Triscone[2], Prof. Cécile Hébert[1]

[1]Electron Spectrometry and Microscopy Laboratory (LSME), Institute of Physics (IPHYS), École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland, [2]Department of Quantum Matter Physics (DQMP), University of Geneva, Geneva, Switzerland

416 WhatEELS upgrade: the software tool based in Python for EELS analysis

Vanessa Costa-Ledesma[1], Daniel del-Pozo-Bueno[1], Francesca Peiró[1], Sònia Estradé[1]

[1]LENS-MIND, Dept. d'Enginyeria Electrònica i Biomèdica and Institute of Nanoscience and Nanotechnology (IN2UB), Universitat de Barcelona, Barcelona, Spain

417 Use of prior knowlege and physics-guided NMF for improved phase segmentation of EDX datasets.

Prof. Cécile Hébert[1], Dr. Adrien Teurtrie[1,2], Dr. Pau Torruella-Besa[1], M. Sebastian Cozma[1], Dr. Hui Chen[1], Dr. James Badro[3], Dr. Duncan T.L. Alexander[1]

[1]EPFL-IPHYS-LSME, Lausanne, Switzerland, [2]Unité Matériaux et Transformations, UMR-CNRS 820, Lille, France, [3]Institut de Physique du Globe, Paris, France

418 3D ED for accurate structure analysis of nanoparticles
Erica Cordero Oyonarte[1], Philippe Boullay[1], Valerie Pralong[1], Luca Rebecchi[2,3], Ilka Kriegel[2]
[1]Normandie Université, ENSICAEN, UNICAEN, CNRS, CRISMAT, Caen, France, [2]Functional Nanosystems, IIT, Genova, Italy, [3]Department of Applied Science and Technology, Politecnico di Torino, Torino, Italy
419 Unsupervised Quantification of large EELS datasets
Prof. Dr. Jo Verbeeck[1,2], Dr. Daen Jannis[1,2], Dr. Wouter Van den Broek[3], Arno Annys[1,2], Dr. Zezhong Zhang[1,2,4], Prof. Dr. Sandra Van Aert[1,2]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]Nano center of excellence, University of Antwerp, Antwerp, Belgium, [3]Thermo Fisher Scientific, Eindhoven, Netherlands, [4]Department of Materials, University of Oxford , Oxford, United Kingdom
420 MAX phase-based nanocomposites for LIBs negative electrodes investigated by multi-approach TEM analysis
Irene Ostroman[1], Dr. Cameron Duncan[1], Mrs. Beatrice Ferrari[1], Mrs. Maria Giulia Bravi[1], Dr. Antonio Gentile[2], Dr. Stefano Marchionna[2], Dr. Chiara Ferrara[1], Dr. Taewon Kim[3], Dr. Changhyun Park[3], Dr. Chanhee Lee[3], Prof. Hyun-Wook Lee[3], Prof. Riccardo Ruffo[1], Prof. Giovanni Maria Vanacore[1]

424 Single-crystal and pentatwinned nanorods reverse the handedness of chiral plasmonic nanocrystals: an electron tomography study
Robin Girod[1], Mr. Kyle Van Gordon[2], Dr. Bing Ni[3,4], Dr. Mikhail Mychinko[1], Mr. Francisco Bevilacqua[2], Prof. Luis Liz-Marzan[2,5,6,7], Prof. Sara Bals[1]
[1]EMAT and NANOlab Center of Excellence, University of Antwerp, Antwerp , Belgium, [2]IC biomaGUNE, Basque Research and Technology Alliance (BRTA), Donostia-San Sebastián, Spain, [3]Physical Chemistry, University of Konstanz, Konstanz, Germany, [4]Present address: Department of Chemical Engineering, University of Michigan, Ann Arbor, USA, [5]Centro de Investigación Biomédica en Red, Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Donostia-San Sebastián, Spain, [6]Ikerbasque, Basque Foundation for Science, Bilbao, Spain, [7]CINBIO, University of Vigo, Vigo, Spain
425 Characterization of Aberration-Corrected Lorentz TEM Applying a Magnetic Field with Objective Lens

Yuki Ninota[1], Yuto Tomita[2], Yuki Ninota[1], Dr. Takeo Sasaki[1], Dr. Shigemasa Ohta[1], Assistant Professor Takehiro Tmaoka[2], Prof. Yasukazu Murakami[2]
[1]JEOL Ltd, 3-1-2 Musashino Akishima, Japan, [2]Kyushu University, 744 Motooka NIshi-ku Fukuoka, Japan

426 Quantification of chirality from electron tomography data

Robin Girod[1], Dr. Mikhail Mychinko[1], Kyle Van Gordon[2], Bing Ni[3,4], Francisco Bevilacqua[2], Luis Liz-Marzan[2,5,6,7], Sara Bals[1]
[1]EMAT and NANOlab Center of Excellence, University of Antwerp, Groenenborgerlaan 171, Antwerp B-2020, Belgium, , , [2]CIC biomaGUNE, Basque Research and Technology Alliance (BRTA), 20014 Donostia-San Sebastián, Spain, , , [3]Physical Chemistry, University of Konstanz, Universitätsstrasse 10, 78457 Konstanz, Germany, , , [4]Present adress: Department of Chemical Engineering, University of Michigan, Ann Arbor, MI USA, , , [5]Centro de Investigación Biomédica en Red, Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), 20014 Donostia-San Sebastián, Spain, , , [6]Ikerbasque, Basque Foundation for Science, 48009 Bilbao, Spain, , , [7]CINBIO, University of Vigo, 36310 Vigo, Spain, ,

427 Femtosecond electron beam probe of ultrafast electronics

Maximilian Mattes[1], Dr Mikhail Volkov[1], Prof Dr Peter Baum[1]
[1]Universität Konstanz, Konstanz, Germany

428 BACKSCATTERED ELECTRON AND X-RAY IMAGING FOR ARRAY TOMOGRAPHY PROVIDES RAPID SPECIMEN CHARACTERISATION AND ROI TARGETING

Pedro Machado[1], George Stonadge[1], Haithem Mansour[1], Alejandra Carbajal[2], Guilherme Neves[3], Juan Burrone[4], Louise Hughes[1], Dr Louise Hughes
[1]Oxford Instruments NanoAnalysis, High Wycombe, United Kingdom, [2]Centre for Ultrastructural Imaging, King's College London, , United Kingdom, [3]MRC Centre for Neurodevelopmental Disorders, Institute of Psychiatry, Psychology and Neuroscience, King's College London, , United Kingdom, [4]Centre for Developmental Neurobiology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, , United Kingdom

429 Fabrication of 2-dimensional disordered assemblies of gold nanoparticles and investigation of localized surface plasmon resonances

Kristina Weinel[1,2], Dr. Johannes Schultz[1], Mohammed Fayis Kalady[1], Dr. Daniel Wolf[1], Dr. Leonardo Agudo Jácome[2], Prof. Dr. Axel Lubk[1]
[1]Leibniz-Institut for Solid State and Materials Research Dresden, Dresden, Germany, [2]Federal Institute for Materials Research and Testing, Berlin, Germany

430 Exploring the infection cycle of Vaccinia virus using 3D EM with the FIB-SEM

Sandra Sara[1]
[1]Université Paris-Saclay, CEA, CNRS, Institute for Integrative Biology of the Cell (I2BC), Gif-Sur-Yvette, France

431 The geometry of STEM tomography

Matthew Weyland[1]
[1]Monash Centre for Electron Microscopy, Monash University, , Australia, [2]Department of Materials Science and Engineering, Monash University, , Australia

432 4D-STEM/PNBD: Fast and easy powder electron diffraction in SEM

Miroslav Slouf[1], Ms. Pavlina Sikorova[2], Mr. Radim Skoupy[2], Mr. Martin Slouf[3], Mrs. Ewa Pavlova[1], Mr. David Rendl[4], Mr. Filip Sroubek[4], Mr. Vladislav Krzyzanek[2]
[1]Institute of Macromolecular Chemistry CAS, Praha, Czech Republic, [2]Institute of Scientific Instruments CAS, Brno, Czech Republic, [3]LiveSystems Ltd., Praha, Czech Republic, [4]Institute of Information Theory and Automation CAS, Praha, Czech Republic

433 In situ size dynamics and manipulation of nanoparticle interaction under electron beam irradiation
Abid Zulfiqar[1], Mari Honkanen[2], Prof. Minnamari Vippola[1,2], Associate Prof. Nonappa Nonappa[1]
[1]Faculty of Engineering and Natural Sciences, Tampere University, FI-33720 Tampere, Finland, [2]Tampere Microscopy Center, Tampere University, FI-33720 Tampere, Finland
434 Molecular mechanism of a bacterial Retron
Researcher Arturo Carabias Del Rey[1], PhD Sarah Camara-Wilpert[2], PhD student Mario Rodríguez-Mestre[2], Academic Coordinator Blanca Lopéz-Méndez[1], Associate Professor Ivo A. Hendriks[1], PhD student Ruiliang Zhao[2], Senior Research Consultant Tillmann Pape[1,3], PhD student Anders Fuglsang[1], Undegraduate student Sean Hoi-Ching Luk[1], Professor Michael L. Nielsen[1], Associate Professor Rafael Pinila Redondo[2], Research director Guillermo Montoya[1]

463 Analytical electron tomography, fine structure EELS and nanoscale X-ray CT of nanoporous Copper materials

Tatiana Kormilina[1], Georg Haberfehlner[2], Samuel Graf[3], Eva-Maria Steyskal[3], Erdmann Spiecker[4], Gerald Kothleitner[1,2]
[1]Graz Centre for Electron Microscopy, Graz, Austria, [2]Institute of Electron Microscopy and Nanoanalysis, Graz University of Technology, Graz, Austria, [3]Institute of Materials Physics, Graz University of Technology, Graz, Austria, [4]Institute of Micro- and Nanostructure Research and Center for Nanoanalysis and Electron Microscopy, Friedrich-Alexander University, Erlangen, Germany

464 M-SIS Software: Automatic tilted series acquisition for environmental (gas, liquid and temperature) multi-scale electron tomography
Dr Louis-Marie Lebas[1], Dr Lucian Roiban[1], Dr Victor Trillaud[1], Dr Mimoun Aouine[2], Professor Karine Masenelli-Varlot[1]
[1]INSA Lyon, Université Claude Bernard Lyon 1, CNRS, MATEIS, UMR5510, Villeurbanne, France, [2]IRCELYON, UMR 5256 CNRS & Université Lyon 1, 2 avenue Albert Einstein, F-69626 , Villeurbanne, France
465 Capturing the diffusion of individual atoms in 3D: heat-induced alloying in Au@Ag nanoparticles
Dr Mikhail Mychinko[1], Dr. Ajinkya Kadu[1], Dr. Annick De Backer[1], Ana Sánchez Iglesias[2], Prof. Dr. Luis Liz-Marzán[2], Prof. Dr. Sara Bals[1]
[1]EMAT and NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [2]Bionanoplasmonics laboratory, CIC BiomaGUNE, San Sebastián, Spain
466 Unveiling the three-dimensional ultrastructure of Poly Lactic Acid (PLA) spherulites by means of electron microscopy
Dr Paola Parlanti[1], Dr Giovanna Molinari[2], Prof Andrea Lazzeri[3,4], Dr Mauro Gemmi[1]
[1]Istituto Italiano di Tecnologia CMI-IIT, Pontedera, Italy, [2]National Research Council CNR-IPCF, Pisa, Italy, [3]University of Pisa, Pisa, Italy, [4]National Interuniversity Consortium of Materials Science and Technology, Florence, Italy
467 High resolution characterization of Y(Mn,In) Blue Chromophoric Oxides
Dr Isobel Bicket[1,2,3], Milenka Andelic[1], Soham Mukherjee[4], Somnath Pal[5], Dipankar Das Sarma[6], Carlo U. Segre[7,8], Gianluigi A. Botton[1,9]
[1]Materials Science and Engineering, McMaster University, Hamilton, Canada, [2]Atominstitut, TU Wien, Vienna, Austria, [3]USTEM, TU Wien, Vienna, Austria, [4]Division of X-ray Photon Science, Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden, [5]MicroNano Systems, Tyndall National Institute, Cork, Ireland, [6]Solid State and Structural Chemistry, Indian Institute of Science, Bangalore, India, [7]Physics & Materials Science and Engineering, Illinois Institute of Technology, Chicago, USA, [8]Center for Synchrotron Radiation Research and Technology, Illinois Institute of Technology, Chicago, USA, [9]Diamond Light Source, Didcot, United Kingdom
468 Twinning in HfO2 nanocrystals
Hongchu Du[1], Prof. Dr. Joachim Mayer[1,2,3]
[1]Forschungszentrum Jülich GmbH, Jülich, Germany, [2]RWTH Aachen University, Aachen , Germany, [3]Jülich Aachen Research Alliance, Jülich, Germany
469 Microscopy techniques show the assembly of nanovesicles around lipid droplets via the tumor protein TPD54
Doctor Sandra Lacas-Gervais[1], Maud Magdeleine[2], Christelle Boscagli[1], Doctor François Orange[1], Doctor Bruno Antonny[2]
[1]Université Côte d'Azur, Centre Commun de microscopie Appliquée, CCMA, Nice, France, [2]Université Côte d'Azur, Institut de Pharmacologie Moléculaire et Cellulaire, IPMC, Valbonne, France
470 Additive effects in phase transformation of calcium phosphate to hydroxyapatite using high-throughput transmission electron microscopy
Miss Johanna Neumann Sørensen[1], Assistant Professor Murat Nulati Yesibolati[1]
[1]Technical University of Denmark (DTU), kgs. lyngby, Denmark
471 In situ TEM thermal study of MBE and CVD GeSn layers: cross-section and plan-view geometries

Karí Martínez[1], Alexey Minenkov[1], Johannes Aberl[2], Moritz Brehm[2], Heiko Groiss[1]
[1]Christian Doppler Laboratory for Nanoscale Phase Transformations, Center for Surface and Nanoanalytics, Johannes Kepler University Linz, 4040 Linz, Austria, [2]Institute of Semiconductor and Solid-State Physics, Johannes Kepler University Linz, 4040 Linz, Austria

472 Illuminating the Microscopic Realm: Application of Resin R221 for CLEM in microbes and plant tissues
Andrea Elizabeth Babu Dominic Cheradil[1], Dr Julia Buchner[1], Dr Matthias Ostermeier[2], Isabella Gantner[1], Jennifer Grünert[1], Prof. Dr. Andreas Klingl[1]
[1]Plant Development & Electron Microscopy, Planegg-Martinsried, Munich, Germany, [2]Department of Molecular Plant Science, Planegg-Martinsried, Munich, Germany
473 4D-STEM and EELS Analysis of Complex C-based Sensor Architectures
Mr Charles Otieno Ogolla[1], Mr Charles Otieno Ogolla[1], Mr Marco Hepp[1], Prof. Benjamin Butz[1], Tristan Zemke
[1]University of Siegen, Siegen, Germany
474 In-situ/ Opernado (S)TEM on Mass Selected Pt Clusters Deposited on CeO2 for CO Oxidation Catalysis
Ajai Raj Lakshmi Nilayam[1], Ramin Shadkam[1], Dr. Carina Maliakkal[1], Mohana Veerraju Kante[1], Prof. Horst Hahn[1], Dr. Di Wang[1], Prof. Christian Kübel[1,2]
[1]Institute of Nanotechnology, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany, [2]Karlsruhe Nano Micro Facility, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany
475 Electron microscopy and X-ray techniques correlative in situ studies in microfluidic conditions on hybrid perovskites
Doctor Claire Jolly[1], Doctor Charles Sidhoum[1], Profesor Ovidiu Ersen[1], Doctor Benedikt Lassalle[2]
[1]Surface and Interface department - IPCMS University of Strasbourg , Strasbourg, France, [2]Synchrotron SOLEIL, Gif sur Yvette, France
476 Atomically Sharp Domain Walls in an Antiferromagnet
Jan Michalička[1], Filip Křížek[2], Sonka Reimers[3], Zdenek Kašpar[2], Ondrej Man[1], Jan Rusz[4], Juan Carlos Idrobo[5], Peter Wadley[3], Tomas Jungwirth[1,3]
[1]CEITEC - Brno University of Technology, Brno , Czech Republic, [2]Institute of Physics of CAS, Prague, Czech Republic, [3]School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom, [4]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden, [5]Center for Nanophase Materials Sciences, ORNL, Oak Ridge, USA
477 Visualizing microbial interactions and CRISPR-Cas interference using FISH applied to environmental archaeal biofilms
Indra Banas[1], Dr Sarah P. Esser[1], Dr. Cristina Moraru[1], Prof. Dr. Alexander J. Probst[1,2,3]
[1]Environmental Metagenomics, Research Center One Health Ruhr of the University Alliance Ruhr, Faculty of Chemistry, University of Duisburg-Essen, Essen, Germany, [2]Centre of Water and Environmental Research (ZWU), University of Duisburg-Essen, Essen, Germany, [3]Center of Medical Biotechnology (ZMB), University of Duisburg-Essen, Essen, Germany
478 Observing Magnetic Skyrmions in Pt/Co/Cu Multilayers using in-situ Lorentz Transmission Microscopy
Nuria Bagues[1,2,3], Binbin Wang[1,2,4], Shuyu Cheng[5], Shekhar Das Das[5], Ziling Li[5], Jacob Freyermuth[5], Camelia Selcu[5], Denis V. Pelekhov[5], Chris Hammel[5], Mohit Randeria[5], Roland Kawakami[5], David W McComb[1,2]
[1]Center for Electron Microscopy and Analysis, The Ohio State University, Columbus , US, [2]Department of Material Science and Engineering, The Ohio State University, Columbus , US, [3]Present address: Alba Synchrotron Light Facility, CELLS, Cerdanyola del Vallès, Spain , [4]Present address: Intel Corporation, Hillsboro, US, [5]Department of Physics, The Ohio State University, Columbus , US
479 Nanoscale T-cell membrane protein imaging across complex topography using accelerated large depth-of-field localisation microscopy

Dr Aleks Ponjavic[1,2], Dr Alex Carr[3], Dr Edward Sanders[3], Dr Mafalda Santos[4], Dr Edward Jenkins[4], Dr James McColl[3], Prof David Klenerman[3], Prof Simon Davis[4], Prof Steven Lee[3]
[1]School of Physics and Astronomy, University of Leeds, Leeds, UK, [2]School of Food Science and Nutrition, University of Leeds, Leeds, UK, [3]Department of Chemistry, University of Cambridge, Cambridge, UK, [4]Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK

480 Active focus stabilisation using astigmatism with universal objective lens compatibility and sub-10 nm precision

Dr Aleks Ponjavic[1,2], Mr Amir Rahmani[1]
[1]School of Physics and Astronomy, University of Leeds, Leeds, UK, [2]School of Food Science and Nutrition, University of Leeds, Leeds, UK

481 Largely improved momentum resolution in STEM-DPC imaging of Si(110) with a segmented detector

Julius Bürger[1], Maja Groll[1], Aladin Ullrich[2], Manfred Albrecht[2], Jörg K. N. Lindner[1]
[1]Paderborn University, Paderborn, Germany, [2]University of Augsburg, Augsburg, Germany

482 Interaction of transduction enhancing peptide nanofibrils with cells and virions assessed by complementary EM techniques

Julia La Roche[1], Lena Wirth-Rauch[2], Laura Zimmermann[2], Dr. Kübra Kaygisiz[3], Prof. Dr. Tanja Weil[3], Prof. Dr. Jan Münch[2,4], Dr. Clarissa Read[1]
[1]Central Facility For Electron Microscopy, Ulm University, Ulm, Germany, [2]Institute of Molecular Virology, Ulm University Medical Center, Ulm, Germany, [3]Department Synthesis of Macromolecules, Max Planck Institute for Polymer Research, Mainz, Germany, [4]Core Facility Functional Peptidomics, Ulm University Medical Center, Ulm, Germany

483 Structure retrieval by parameterised inverse multislice accounting for partial coherence and thermal effects

Prof. Dr. Knut Müller-Caspary[1], Dr. Benedikt Diederichs[1,2], Ziria Herdegen[1], Achim Strauch[1,3]
[1]LMU München, Munich, Germany, [2]HMGU München, Munich, Germany, [3]Forschungszentrum Jülich, Jülich, Germany

484 Temperature-dependence of beam-driven dynamics in graphene-fullerene sandwiches

Kevin Strobel[1,2], Michael Schlegel[1,2], Mitisha Jain[3], Dr. Silvan Kretschmer[3], Dr. Arkady V. Krasheninnikov[3], Prof. Dr. Jannik C. Meyer[1,2]
[1]Institute of Applied Physics University of Tübingen, Tübingen, Germany, [2]NMI Natural and Medical Sciences Institute at the University of Tübingen, Reutlingen, Germany, [3]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

485 Viral replication organelles revisited by cryo-electron microscopy

Georg Wolff[1], Ronald Limpens[1], Nina de Beijer[2], Abraham Koster[1], Eric Snijder, Montserrat Bárcena[1]
[1]Section Electron Microscopy, Department of Cell and Chemical Biology, Leiden University Medical Center, Leiden, The Netherlands, [2]Molecular Virology Laboratory, Leiden University Center of Infectious Diseases, Leiden University Medical Center, Leiden, The Netherlands

486 Influence of dynamical diffraction on DPC measurements of 2D materials

Maja Groll[1], Julius Bürger[1], Prof. Dr. Jörg K. N. Lindner[1]
[1]Paderborn University, Paderborn, Germany

487 Sensing the Invisible: Ultrathin (UT) Membrane Chip for In-Situ Microscopy

Professor, Director Vinayak Dravid[1]
[1]Materials Science & Engineering, NUANCE Center, Northwestern University , Evanston, United States

488 Impact of Clostridium botulinum C2 Toxin on the ultrastructure of cells

Jasmin Christine Bellemann[1], Joscha Borho[2], Dr. Clarissa Read[1], Prof. Dr. Paul Walther[1], Prof. Dr. Holger Barth[2]

[1]Central Facility for Electron Microscopy, Ulm University, Ulm, Germany, [2]Institute of Experimental and Clinical Pharmacology, Toxicology and Pharmacology of Natural Products, Ulm University Medical Center, Ulm, Germany

489 Nondestructive structural characterization of 2D materials by hybrid pixel direct detector

Dr. Jakub Holzer[1], Dr. Chris Stephens[2], Dr. Tomas Vystavel[1]
[1]ThermoFisher Scientific, Brno, Czech Republic, [2]ThermoFisher Scientific, East Grinstead, United Kingdon

490 Elucidating functionalities of N-doped carbonaceous materials by means of in-situ TEM

Dr Nadezda Tarakina[1], Dr. Diana Piankova[1], Dr. Hannes Zschiesche[1], Dr. Jing Hou[1], Prof. Dr. Markus Antonietti[1]
[1]Department of Colloid Chemistry, Max Planck Institute of Colloids and Interfaces, Potsdam, Germany

491 Accessible STEM-DPC Imaging Using ADF Detector Allowing in-situ Magnetic Reversal Studies

Julie Marie Bekkevold[1,2], Dr. Magnus Nord[1]
[1]Norwegian University of Science and Technology, Trondheim, Norway, [2]Trinity College Dublin, Dublin, Ireland

492 Label-free imaging of virus-cell interactions using 200 Hz ROCS microscopy

Dominik Huber[1], Prof. Dr. Alexander Rohrbach[1]
[1]Lab for Bio- and Nano-Photonics, University of Freiburg, Freiburg, Germany

493 The ultrastructural analysis of plant-microbe interfaces

Isabella Gantner[1], Dr. Julia Buchner[1], Prof. Dr. Andreas Klingl[1]
[1]Plant Development and Electron microscopy, Ludwig-Maximilians-Universität, Munich, Germany

494 Event-responsive Beam-modulated STEM with Multi-frame and Sparse Scanning

Dr Jonathan Peters[1,2,3], Matthew Mosse[1,2], Bryan Reed[4], Daniel Masiel[4], Michele Conroy[5], Lewys Jones[1,2,3]
[1]Advanced Microscopy Laboratory (CRANN), Trinity College Dublin, Dublin, Ireland, [2]School of Physics, Trinity College Dublin, Dublin, Ireland, [3]turboTEM Ltd., , Ireland, [4]Integrated Dynamic Electron Solutions, Inc., Pleasanton, USA, [5]Department of Materials, London Centre of Nanotechnology, Imperial Henry Royce Institute, Imperial College London, London, UK

495 Identification of the phases resulting from the thermal crystallization of Ge-rich GeSbTe alloys using EELS

Dr. Minh Anh Luong[1], Dr. Eloïse Rahier[1], Dr. Sijia Ran[1], Dr. Alain Claverie[1]
[1]CEMES-CNRS and University of Toulouse, 29 Rue Jeanne Marvig, 31055 Toulouse, France

496 Multi-scale electron tomography in liquid state and its application to the study of beam-sensitive nanomaterials

Dr. Louis Marie Lebas[1], Dr Lucian Roiban[1], Dr. Victor Trillaud[1], Dr. Mimoun Aouine[2], Professor Karine Masenelli-Varlot[1]
[1]INSA Lyon, Université Claude Bernard Lyon 1, CNRS, MATEIS, UMR5510, Villeurbanne, France, [2]IRCELYON, UMR 5256 CNRS & Université Lyon 1, 2 avenue Albert Einstein, F-69626 , Villeurbanne, France

497 In-situ nucleation of silicon particles using environmental transmission electron microscopy

Dr Lucian Roiban[1], Dr. Cynthia Cibaka-Ndaya[2], Dr. Kevin O'Connor[3], M. Emmanuel Opeyemi Idowu[2], Professor Jonhatan G.-C. Veinot[3], Dr. Glenna L. Drisko[2]
[1]INSA Lyon, Université Claude Bernard Lyon 1, CNRS, MATEIS, UMR5510, Villeurbanne, France, [2]ICMCB, UMR 5026, CNRS, Univ. Bordeaux, Bordeaux INP, Pessac F-33600, France, [3]Department of Chemistry, The University of Alberta, Edmonton, Canada

498 Heating effects in Bi-doped Cu nanowires for spintronics: atomic resolution in-situ insights

Miss Alejandra Guedeja-Marron[1,2], Dr Matilde Saura-Muzquiz[1], Miss Ines Garcia-Manuz[3], Dr Juan I. Beltran[1], Dr Henrik L. Andersen[4], Dr Lunjie J. Zeng[5], Dr Alok Ranjan[5], Prof. Eva Olsson[5], Dr Paolo Perna[6], Prof. Lucas Perez[1,6], Prof. Maria Varela[1,2]
[1]Dept. Fisica de Materiales, Complutense University of Madrid, Madrid, Spain, [2]Instituto Pluridisciplinar, Complutense University of Madrid, Madrid, Spain, [3]Universidad Autonoma de Madrid, Madrid, Spain, [4]Instituto de Ciencia de Materiales de Madrid (ICMM) - CSIC, Madrid, Spain, [5]Chalmers University of Technology, , Sweden, [6]Instituto Madrileño de Estudios Avanzados – IMDEA Nanociencia, Madrid, Spain

499 Transfer of Nanomaterials for in-situ TEM with electrical Currents

Simon Hettler[1,2], Mohammad Furqan[1,2], Raul Arenal[1,2,3]
[1]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, Zaragoza, Spain, [3]Araid Foundation, Zaragoza, Spain

500 Zernike Phase Plates for aberration-corrected TEM in Material Science

Simon Hettler[1,2], Raul Arenal[1,2,3]
[1]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza. Zaragoza, Zaragoza, Spain, [3]Araid Foundation, Zaragoza, Spain

501 Enhanced time resolution with a room-temperature energy dispersive X-ray PIN photodiode detector

Luca Serafini[1,2], Mr. Mylo Gijbels[1,2], Prof. Dr. Jo Verbeeck[1,2]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium

502 Development and application of In-situ atomic-scale straining&heating&biasing platform for TEM

Dr. Zhipeng Li[1,2], Dr. Jianfei Zhang[1], Dr. Haixin Li[1,2], Prof. Shengcheng Mao[1], Prof. Xiaodong Han[3], Prof. Ze Zhang[4]
[1]Beijing University of Technology, Beijing, China, [2]Bestron Science&Technology Co., Ltd., Beijing, China, [3]Southern University of Science and Technology of China, Shenzhen, China, [4]Zhejiang University, Hangzhou, China

503 Sn Alloying Impact on Structural and Electronic Properties of Core-Shell Ge-GeSn Nanowires: A TEM Study

Milenka Andelic[1], Dr. Alexandre Pofelski[1,4], Dr. Isobel Bicket[1,2,3], Dr. Simone Assali[5], Dr. Sebastian Koelling[5], Dr Lo Luo[5], Dr. Oussama Moutanabbir[5], Dr. Gianluigi Botton[1,6]
[1]McMaster University, Hamilton, Canada, [2]Atominstitut, TU Wien, Vienna, Austria, [3]University Service Centre for Transmission Electron Microscopy, TU Wien, Vienna, Austria, [4]Brookhaven National Laboratory, Upton, USA, [5]Ecole Polytechnique Montreal, Montreal, Canada, [6]Diamond Light Source, Oxfordshire, UK

504 Cryo-ET Structures of Huntingtin-Actin Complexes Reveal that Huntingtin Organizes Actin Cytoskeleton in Neurons

Professor Ji-Joon Song[1]
[1]Korea Advanced Institute of Science and Technology, Dajeon, South Korea

505 Ultrastructural investigation of human cytomegalovirus tegument protein UL71 and its role in secondary envelopment

Benedikt Küß[1], Annika Metzner[2], M.Sc. Laura Cortez Rayas[2], Prof. Dr. Paul Walther[1], Dr. Gregor Neusser[3], apl. Prof. Dr. Christine Kranz[3], Dr. Clarissa Read[1,2], apl. Prof. Dr. Jens von Einem[2]

[1]Central Facility for Electron Microscopy, Ulm University, Ulm, Germany, [2]Institute of Virology, Ulm University Medical Center, Ulm, Germany, [3]Institute of Analytical and Bioanalytical Chemistry, Ulm University, Ulm, Germany

506 Strain mapping and simulation of transistor structures in a 22nm FDSOI technology

Dirk Utess[1], Dominik Martin Kleimaier[1], Etienne Billan[1], Tashfain Youssuf[1], Zhixing Zhao[1], Thorgund Nemec[1], Dr. Moritz Andreas Meyer[1], Dr. Jochen Rinderknecht[1]
[1]GlobalFoundries, Dresden, Germany

507 Revolutionizing Electron Microscopy Through Intuitive Language-Driven Interfaces: The Emergence of the EM CoPilot

Remco Geurts[1], Pavel Potocek[1], Remco Schoenmakers[1], Giovanni Mariotta[1]
[1]ThermoFisher Scientific, Eindhoven, Netherlands

508 Structural basis of rotavirus spike proteolytic activation

Dr Dunia Asensio-Cob[1], Dr Carlos Perez-Mata[2], Dr Josue Gomez-Blanco[3], Dr Javier Vargas[3], Dr Javier M Rodriguez[2], Dr Daniel Luque Buzo[4]
[1]The Hospital for Sick Children, Toronto, Canada, [2]National Centre for Biotechnolgy, Madrid, Spain, [3]Universidad Complutense de Madrid, Madrid, Spain, [4]The University of New South Wales, Sydney, Australia

509 Cryo electron tomography of impregnated mesoporous catalyst supports

Jason Heinrichs[1,2], Mr. Rick Joosten[2,3], Ms. Jovana Zečević[4], Mr. Thomas Weber[1,4], Mr. Emiel Hensen[1], Mr. Heiner Friedrich[2,3]
[1]Laboratory of Inorganic Materials and Catalysis, Department of Chemical Engineering and Chemistry, Eindhoven University of Technology (TU/e), Eindhoven, The Netherlands, [2]Center for Multiscale Electron Microscopy, Department of Chemical Engineering and Chemistry, Eindhoven University of Technology (TU/e), Eindhoven, The Netherlands, [3]Laboratory of Physical Chemistry, Department of Chemical Engineering and Chemistry, Eindhoven University of Technology (TU/e), , The Netherlands, [4]Shell Projects and Technology, Energy Transition Campus Amsterdam (ETCA), Amsterdam, The Netherlands

510 Structure-activity relationship of Pt nanoparticles during the CO oxidation reaction

Christian Fink Elkjær[1], Ph.d. Sebastian Jespersen[1], Søren Vendelbo[2], Christian D. Damsgaard[3], Patricia Koymann[4], Ib Chorkendorff[3], Stig Helveg[3]
[1]Topsoe A/S, Kgs. Lyngby, Denmark, [2]Technological Institute, Taastrup, Denmark, [3]Technical University of Denmark, Kgs. Lyngby, Denmark, [4]University of Cape Town, Rondebosch, South Africa

511 Advanced imaging reveals new lipid droplets dynamics in the malaria parasite Plasmodium falciparum

Jiwon Lee[1,2], Professor Kai Matuschewski[3], Associate Professor Giel van Dooren[2], Professor Alexander G. Maier[2], Assoc. Prof. Melanie Rug[1]
[1]Centre for Advanced Microscopy, The Australian National University, Canberra, Australia, [2]Research School of Biology, The Australian National University, Canberra, Australia, [3]Molecular Parasitology, Humboldt University, Berlin, Germany

512 Atom-counting for heterogeneous nanostructures using multimodal STEM

Dr Annick De Backer[1], Dr Zezhong Zhang[1], Dr Ana Sánchez-Iglesias[2], Prof Luis M. Liz-Marzán[2,3], Prof Peter D. Nellist[4], Prof Sara Bals[1], Duygu G. Şentürk[1], Dr Yansong Hao[1], Prof Scott Findlay[5], Prof Sandra Van Aert[1]
[1]EMAT & NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [2]CIC biomaGUNE, Basque Research and Technology Alliance (BRTA), Donostia-San Sebastián, Spain, [3]Ikerbasque, Basque Foundation for Science, Bilbao, Spain, [4]Department of Materials, University of Oxford, Oxford, United Kingdom, [5]School of Physics and Astronomy, Monash University, Melbourne, Australia

513 Microfabricated Sample Carrier for Cryogenic Electron Microscopy

Dr Vasilis Papadimitriou[1], Dr Evgeniya Pechnikova[1], Mr Merijn Pen[1], Hugo Pérez-Garza[1]
[1]DENSsolutions, Delft, The Netherlands

514 Understanding phase and chemical transitions in Ge-rich GeSbTe based phase change memory: a (S)TEM tribute

Sijia RAN[1], Minh-Anh LUONG[1], Eloïse RAHIER[1], Elisa PETRONI[2], Daniel BENOIT[3], Alain CLAVERIE[1]
[1]CEMES-CNRS and University of Toulouse, Toulouse, France, [2]STMicroelectronics, Agrate Brianza, Italy, [3]STMicroelectronics, Crolles, France

515 Mechanism of WS2 nanotube formation revealed by in-situ/ex-situ imaging and cross-sectional sequences

Dr. Vojtech Kundrat[1,2], Dr. Libor Novak[2], Dr. Kristyna Bukvisova[2,3], Assoc. Prof. Miroslav Kolibal[3], Prof. Reshef Tenne[1]
[1]Weizmann Institute of Science, Rehovot, Israel, [2]Thermo Fisher Scientific, Brno, Czech Republic, [3]Brno University of Technology, Brno, Czech Republic

516 Data clustering for chemical and structural analysis of nanostructured films

Dr. Giovanni Bertoni[1], Paolo Rosi[1], Gian Carlo Gazzadi[1], Vincenzo Grillo[1], Eleonora Spurio[1], Paola Luches[1], Riccardo Magrin Maffei[1], Stefania Benedetti[1]
[1]CNR - Istituto Nanoscienze, Modena, Italy

517 In-situ TEM Investigations of the electrical Breakdown of Nanotubes made of Misfit-Layered Compounds

Simon Hettler[1,2], MB Sreedhara[3], Reshef Tenne[4], Raul Arenal[1,2,5]
[1]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, Zaragoza, Spain, [3]Solid State and Structural Chemistry Unit, Indian Institute of Science, Bengaluru, India, [4]Department of Molecular Chemistry and Materials Science, Weizmann Institute of Science, Rehovot, Israel, [5]Araid Foundation, Zaragoza, Spain

518 Optimising a modern high performance FE-SEM for multimodal vEM

Dr Eudri Venter[1], Dr. Sonja Gürster[2]
[1]JEOL UK, Welwyn Garden City, United Kingdom, [2]JEOL (Germany) GmbH, Freising, Deutschland

519 TEM and photocurrent response of FE BTO thin films heterostructure on silicon for Neuromorphic applications

Myriam H. Aguirre[1,2,3], Miguel Rengifo[2], Diego Rubi[4]
[1]Departamento de Física de la Materia Condensada, Universidad de Zaragoza, Zaragoza, Spain, [2]INMA-Instituto de Nanociencia y Materiales de Aragón, Universidad de Zaragoza-CSIC, Zaragoza, Spain, [3]Laboratorio de Microscopías Avanzada, Universidad de Zaragoza, Zaragoza, Spain, [4]Instituto de Nanociencia y Nanotecnología (INN), Comisión Nacional de Energía Atómica-Consejo Nacional de Investigaciones Científicas y Técnicas (CNEA-CONICET), Buenos Aires, Argentina

520 Scanning electron diffraction reveals the molecular ordering of polysaccharides at the nanoscale

Mr. Mathias Nero[1], Dr. Tom Willhammar[1]
[1]Stockholm University, Stockholm, Sweden

521 Two-photon line-scanning structured illumination microscopy (LIL-SIM) for super-resolution imaging in deep tissue

Patrick Byers[1,2], M.Sc. Thomas Kellerer[1], Prof. Dr. Thomas Huser[2], Prof. Dr. Thomas Hellerer[1]
[1]Multiphoton Imaging Lab, Munich University of Applied Sciences, Munich, Germany, [2]Biomolecular Photonics, Department of Physics, University of Bielefeld, Bielefeld, Germany

522 Study of nuclear materials for silicon carbide composite fuel claddings via STEM, EDX and EELS

Phd Student Hector Guerra Yanez[1], PhD Student Andrea Stinchelli[2,3], Doctor Fabio Di Fonzo[3], Professor Per O.Å. Persson[1]

[1]Department of Physics, Chemistry and Biology, University of Linköping, Linköping, Sweden, [2]Department of Energy, Politecnico di Milano, Milan, Italy, [3]X-nano s.r.l., Milan, Italy

523 Functional chemistry of minimally altered organic matter in the meteorite Winchcombe probed by monochromated EELS

Dr Aleksander Buseth Mosberg[1], Dr Christian Vollmer[2], Dr Demie Kepaptsoglou[1,3], Dr Jan Leitner[4,5], Dr Khalil El Hajraoui[1], Dr Ashley J. King[6], Ms. Charlotte L. Bays[6,7], Dr Paul F. Schofield[6], Dr Tohru Araki[8,9], Prof. Quentin M. Ramasse[1,10]

[1]SuperSTEM Laboratory, SciTech Daresbury, Daresbury, UK, [2]Institut für Mineralogie, University of Münster, Münster, Germany, [3]School of Physics, Engineering and Technology, University of York, Heslington, UK, [4]Institut für Geowissenschaften, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany, [5]Max Planck Institute for Chemistry, Particle Chemistry Department, Mainz, Germany, [6]Planetary Materials Group, Natural History Museum, , UK, [7]Department of Earth Sciences, Royal Holloway, University of London, Egham, UK, [8]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, UK, [9]National Institutes of Natural Sciences, Institute for Molecular Science, UVSOR Synchrotron Facility, Okazaki, Japan, [10]School of Chemical and Process Engineering and School of Physics and Astronomy, University of Leeds, Leeds, UK

524 Elucidation of Structure-catalytic Activity of Nickel-based Nanomaterial for Electrocatalytic Water Splitting

Dr. Jean Marie Vianney Nsanzimana[1], Charles Otieno Ogolla[1], Max Kasper[1], Prof. Manuela Killian[2], Prof. Butz Benjamin[1]

[1]Micro- and Nanoanalytics Group, University of Siegen, Siegen, Germany, [2]Chemistry and Structures of Novel Materials, University of Siegen, Siegen, Germany

525 Assessing the Accuracy of Strain Mapping using 4D-STEM

Petr Vacek[1], Paul Midgley[1]

[1]Department of Materials Science and Metallurgy, University of Cambridge, 27 Charles Babbage Road, Cambridge, United Kingdom

526 Cryogenic electron microscopy for native state analysis of soft- and nano-materials

Dario Luis Fernandez Ainaga[1], Teresa Roncal-Herrero[1], Martha Ilett[1], Stuart Micklethwaite[1], Zabeada Aslam[1], Eleena Naveed[1], James Hitchcock[1], Cheng Cheng[1], Benjamin Lobel[1], Olivier Cayre[1], Dr Nicole Hondow[1]

[1]University of Leeds, Leeds, UK

527 PVA/PEG-based nanofibers with Au nanoparticles for treatment of chronic woundss

Dr. Elena Filova[1], Prof. Petr Slepicka[2], Dr. Nikola Slepickova Kasalkova[2], Prof. Vera Jencova[3], Ing. Maxim Lisnenko[3], Ing. Sarka Hauzerova[3], Prof. David Lukáš[3], Dr. Jana Nebesarova[4], Dr. Silvie Rimpelova[5,6], Mrs. Yu-Chieh Wu[1], Prof. Lucie Bacakova[1]

[1]Laboratory of Biomaterials and Tissue Engineering, Institute of Physiology of the Czech Academy of Sciences, Prague, Czech Republic, [2]Department of Solid State Engineering, University of Chemistry and Technology Prague, Prague, Czech Republic, [3]Faculty of Science, Humanities and Education, Department of Chemistry, Technical University of Liberec , Liberec, Czech Republic, [4]Laboratory of Electron Microscopy, Faculty of Science, Charles University, Prague, Czech Republic, [5]Department of Biochemistry and Microbiology, University of Chemistry and Technology Prague, Prague, Czech Republic, [6]Department of Tissue Engineering, Institute of Experimental Medicine of the Czech Academy of Sciences, Prague, Czech Republic

528 Fine-tuning the Size of ZIF-L Nanosheets Through Controlled Synthesis

Sara Talebi Deylamani[1], Dr. Giuseppe Di Palma[1], Dr. Pritam Banerjee[1], Prof. Kasper S. Pedersen[2], Prof. Joerg R. Jinschek[1]

[1]DTU Nanolab, Technical University of Denmark (DTU), Lyngby, , Denmark, [2]DTU Chemistry, Technical University of Denmark (DTU), Lyngby, , Denmark

529 How to better understand ZrCu Thin Films Metallic Glasses recrystallization: a TEM in situ characterization?
Pr. Philippe Steyer[1]
[1]MateIS Laboratory, SNMS Microscopy group, INSA de Lyon, Villeurbanne, France
530 Momentum resolved band gap measurement by high energy resolution electron energy loss spectroscopy
Dr Dileep Krishnan[1], Dr. Ioannis Iatrakkis
[1]Thermofisher Scientific, Eindhoven, Netherlands
531 Probing the Sensitive Reactions of Battery Cathodes Through (Cryogenic) Atom Probe Tomography
Dr. Mahander Pratap Singh[1], Mr. Eric V Woods, Prof. Baptiste Gault
[1]Max-Planck-Institute for Sustainable Materials, (formerly Max-Planck-Institute für Eisenforschung), Düsseldorf, Germany
532 FOUR MICROSCOPY METHODS UNVEIL LIVER FENESTRATIONS: CORRELATIVE SEM, SIM, STED, AFM TARGETING SINGLE CELL TYPE
Dr Hab. Bartlomiej Zapotoczny[1], dr Karolina Szafranska[2], prof. Stefan Chlopicki[3], prof. Marek Szymonski[4], prof. Balpreet S. Ahluwalia[2], prof. Malgorzata Lekka[1], prof. Peter McCourt[2]
[1]Institute of Nuclear Physics Polish Academy of Sciences , Krakow, Poland, [2]UiT-The Arctic University of Norway, Tromsø, Norway, [3]Jagiellonian Centre for Experimental Therapeutics, Jegiellonian University , Krakow, Poland, [4]Marian Smoluchowski Institute of Physics, Jegiellonian University, Krakow, Poland
533 Investigating the formation of surface reconstruction layers in Ni-rich cathode materials using STEM

Lara Ahrens[1,2], Kilian Vettori[3], Dr. Shibabrata Basak[4], Prof. Dr. Rüdiger-A. Eichel[4], Prof. Dr. Joachim Mayer[1,2]
[1]Central Facility for Electron Microscopy (GFE), RWTH Aachen University, Aachen, Germany, [2]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, Jülich, Germany, [3]Physical-Chemical Institute, Justus-Liebig-University, Gießen, Germany, [4]Institute of Energy and Climate Research (IEK-9), Forschungszentrum Jülich , Jülich, Germany
534 Breaking the limits of functional Atomic Force Microscopy imaging using Focused Electron Beam Induced Deposition
Michele Brugger-Hatzl[1], Lukas Seewald[2], Robert Winkler[2], David Kuhness[2], Michael Huth[3], Sven Barth[3], Harald Plank[1,2,4]
[1]Graz Centre for Electron Microscopy, Graz, Austria, [2]Christian Doppler Laboratory - DEFINE, Graz University of Technology, Graz, Austria, [3]Institute of Physics, Goethe University, Frankfurt am Main, Germany, [4]Institute of Electron Microscopy and Nanoanalysis, Graz University of Technology, Graz, Austria
535 Novel polymer thin film fabrication for graphitization studied by in situ transmission electron microscopy
Chloé Chemin[1], Dr. Babak Rezaei[1], Dr. Alice Bastos da Silva Fanta[1], Dr. Ada-Ioana Bunea[1], Prof. Stephan Sylvest Keller[1], Prof. Thomas Willum Hansen[1]
[1]National Centre for Nano Fabrication and Characterization, DTU Nanolab, Technical University of Denmark, 2800 Kongens Lyngby, Denmark
536 Single-cell pharmacology: atomic force microscopy and spectroscopy for multiparametric imaging of drug-induced alterations in vitro
Dr Hab. Bartlomiej Zapotoczny[1], dr Izabela Czyzynska-Cichon[2], professor Stefan Chlopicki[2], professor Malgorzata Lekka[1]

[1]Institute of Nuclear Physics Polish Academy of Sciences, Krakow, Poland, [2]Jagiellonian Centre for Experimental Therapeutics, Jegiellonian University, Krakow, Poland

537 Segregation to Creep-induced Planar Faults in Ni-base Single Crystal Superalloys

Zhongmin Long[1], Dr. David Bürger[2], Dr. Christian Dolle[1], Yuting Dai[3], Prof. K. V. Vamsi[4], Prof. Yolita M. Eggeler[1]
[1]Microscopy of Nanoscale Structures & Mechanisms,Laboratory for Electron Microscopy, Karlsruhe Institute of Technology, Karlsruhe, Germany, [2]Institute for Materials, Ruhr-Universität Bochum, Bochum, Germany, [3]Institute of Nanotechnology, Karlsruhe Institute of Technology, Karlsruhe, , Germany, [4]Metallurgical Engineering and Materials Science, Indian Institute of Technology Indore, Indore, India

538 Polar textures in multiferroic BiFeO3-based superlattices

Dr. Razvan Burcea[1], Oana Condurache[1], Mouna Khiari[2], Maxime Vallet[1], Stephane Roux[3], Pascal Ruello[4], Brahim Dkhil[1], Houssny Bouyanfif[2]
[1]Université de Paris-Saclay, CentraleSupelec, SPMS, Gif-sur-Yvette, France, [2]LPMC EA2081, Université de Picardie Jules Verne, Amiens, France, [3]Université de Paris-Saclay, ENS Paris-Saclay, LMPS, Gif-sur-Yvette, France, [4]IMMN, Le Mans Université, , France

539 Characterization of inorganic food additives and pearlescent pigments in sprays for food decoration by STEM-EDX

Noa Olluyn[1,2], Dr. Eveline Verleysen[1], Lisa Siciliani[1,2], Dr. Daniel Arenas Esteban[2], Dr. Stella Mathioudaki[1], Dr. Subhalakshmi Sharma[1], Joris Van Loco[1], Prof. Dr. Sara Bals[2], Dr. Jan Mast[1]
[1]Sciensano, Uccle, Belgium, [2]EMAT, University of Antwerp, Antwerp, Belgium

540 Optimizing data acquisition and interpretation in atomically resolved STEM spectrum imaging

Yi Wang[1]
[1]Center for Microscopy and Analysis, Nanjing University of Aeronautics and Astronautics, Nanjing, China

541 Progress in Magnon EELS simulations

Dr. José Ángel Castellanos-Reyes[1], Dr. Paul Zeiger[1], Dr. Ján Rusz[1]
[1]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

542 Study of Lithiation Dynamics in Cathode Materials by in situ TEM Electrochemical Liquid Technics.

Student Kevyn Gallegos-Moncayo[1], Justine Jean[1,2], PhD Nicolas Folastre[1], PhD Arash Jamali[1,2], PhD Arnaud Demortière[1,2,3]
[1]CNRS-LRCS, Amiens, France, [2]RS2E-French Research Network on Electrochemical Energy Storage, Amiens, France, [3]ALISTORE- European Research Institute, Amiens, France

543 Towards Quantitative Liquid Phase Electrochemistry for Understanding Electrochemical Processes

Shibabrata Basak[1], Junbeom Park[1], Hongyu Sun[2], Hugo Pérez Garza[2], Eva Jodat[1], André Karl[1], Rüdiger-A Eichel[1]
[1]Institute of Energy and Climate Research, Fundamental Electrochemistry (IEK-9), Forschungszentrum Jülich GmbH, Jülich, Germany, [2]DENSsolutions B.V., Delft, The Netherlands

544 Correlative cryo-bioimaging to study coronavirus replication organelles

Mr Patrick Phillips[1,2,3], Prof Philippa Hawes[4], Prof Maria Harkiolaki[2], Dr Dan Clare[2], Prof Jonathan Grimes[3], Dr Helena Maier[1]
[1]The Pirbright Institute, Woking, United Kingdom, [2]Diamond Light Source, Didcot, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]The Francis Crick Institute, London, United Kingdom

545 Enhancing tool performance with complex microscopy investigation of additively manufactured M2 steel and composites

Ing. Ph.d. Martina Koukolíková[1], Mr. Pavel Podaný[1], Mr. Miroslav Urbánek[1], Mr. Michal Brázda[1], Mrs. Ivana Poláková[1], Mr. Josef Hodek[1]
[1]COMTES FHT a.s., Dobrany, Czech Republic

546 Leveraging gas-cell in situ electron microscopy to track atmosphere-dependent reversible transformations in reducible oxides

Postdoc Ramon Manzorro[1], Irene Piedra[1], Carmen Mora[1], Jose A. Perez-Omil[1], Jose J. Calvino[1], Miguel Lopez-Haro[1], Ana Hungria[1]
[1]Departamento de Ciencias de los Materiales e Ingeniería Metalúrgica y Química Inorgánica, Facultad de Ciencias, Universidad de Cádiz, Puerto Real, Spain

547 In-situ STEM-EELS observations on heating TiO2-x nanoparticles for solar and electrocatalytic applications.

Dr Khalil El Hajraoui[1,2], Dr Leonardo Lari[2,3], Mrs Fayzah Talbi[2,3], Prof. Richard Douthwaite[4], Prof Quentin. M Ramasse[1,5], Prof Vlado. K Lazarov[2,3], Dr Demie Kepaptsoglou[1,2]
[1]SuperSTEM Laboratory, SciTech Daresbury, Daresbury, United Kingdom, [2]School of Physics, Engineering and Technology, University of York, York, United Kingdom, [3]Jeol York Nanocentre, University of York, York, United Kingdom, [4]Department of Chemistry, University of York, York, United Kingdom, [5]School of Chemical and Process Engineering & School of Physics and Astronomy, University of Leeds, Leeds, United Kingdom

548 ACOM characterization of phase transitions during overageing of aluminium alloys using a direct electron detector

Dr Arthur Després[1], Thomas Perrin[1], Dr Pierre Heugue[2], Pr Alexis Deschamps[1], Dr Fréderic de Geuser[1]
[1]Univ. Grenoble Alpes, CNRS, Grenoble INP, SIMaP, F-38000 Grenoble, France, [2]Safran Transmission Systems, Colombes, France

549 Simulations of phonon and magnon EELS/EEGS including dynamical effects and multiple inelastic excitations

José Ángel Castellanos-Reyes[1], Paul Zeiger[1], Jan Rusz[1]
[1]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

550 Direct Visualization of Temperature Induced Phase Separation of Completely Miscible Au-Pd Alloy by In-Situ TEM

Dr. Abhijit Roy[1,2], Dr. Simon Hettler[1,2], Dr. Raul Arenal[1,2,3]
[1]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, Zaragoza, Spain, [3]ARAID Foundation Zaragoza , Zaragoza, Spain

551 4D-STEM Post measurement machine learning enhanced aberration correction for amorphous and magnetic samples

Maximilian Töllner[1], Xiaoke Mu[3], Di Wang[1], Christian Kübel[1,2]
[1]Institute of Nanotechnology - KIT, Karlsruhe, Germany, [2]KNMFi, Karlsruhe, Germany, [3]School of Materials and Energy and Electron Microscopy Centre, Lanzhou University, Lanzhou, China

552 New insights into optical property characterization of 2D semiconductor materials through time-correlated photon/electron spectroscopies

Florian Castioni[1], Yves Auad[1], Nadezda Varkentina[1], Alissa Freilinger[1], Steffi Y. Woo[1], Noémie Bonnet[1], Jean-Denis Blazit[1], Xiaoyan Li[1], Marcel Tencé[1], Kenji Watanabe[2], Takashi Taniguchi[3], Odile Stéphan[1], Mathieu Kociak[1], Luiz H. G. Tizei[1]
[1]Université Paris-Saclay, CNRS, Laboratoire de Physique des Solides, Orsay, France, [2]Research Center for Electronic and Optical Materials, National Institute for Materials Science, 1-1 Namiki, , Japan, [3]Research Center for Materials Nanoarchitectonics, National Institute for Materials Science, 1-1 Namiki, , Japan

553 Laser particle acceleration in an ultrafast scanning electron microscope

Leon Brückner[1], Tomas Chlouba[1], Roy Shiloh[1], Stefanie Kraus[1], Julian Litzel[1], Peter Hommelhoff[1]
[1]Physics Department, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany
554 Direct Visualization of Temperature Induced Phase Separation of Completely Miscible Au-Pd Alloy by In-Situ TEM
Dr. Abhijit Roy[1,2], Dr. Simon Hettler[1,2], Dr. Raul Arenal[1,2,3]
[1]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, Zaragoza, Spain, [3]ARAID Foundation Zaragoza , Zaragoza, Spain
555 Influence of the loss function on gradient-based iterative ptychographic reconstructions in 4D-STEM
Max Leo Leidl[1,2], Carsten Sachse[2,3], Knut Müller-Caspary[1,2]
[1]Ludwig Maximilian University of Munich, Munich, Germany, [2]Ernst Ruska-Centre, Forschungszentrum Jülich GmbH, Jülich, Germany, [3]Heinrich Heine Universitöt Düsseldorf, Düsseldorf, Germany
556 The organization of organic/biominerals in the nanostructured 3D photonic crystals in insects' scales
Dr. Yin Chang[1], Dr. Hsiang-Han Tseng[2], Dr. Luca Bertinetti[1], Dr. Michaela Wilsch-Bräuninger[3], Prof. Yael Politi[1]
[1]B CUBE - Center for Molecular Bioengineering, Technische Universität Dresden, Dresden, Germany, [2]Thermo Fisher Scientific, 1, The Felbridge Centre, Imberhorne Lane, East Grinstead, West Sussex, UK, [3]Max Planck Institute of Molecular Cell Biology and Genetics, , Germany
557 Multi-Convergence-Angle Ptychography with Simultaneous Strong Contrast and High Resolution
Mr. Wei Mao[1,2], Mr. Weiyang Zhang[2], Dr. Chen Huang[3], Prof. Liqi Zhou[1,2,5], Dr. Judy Kim[3,4], Prof. Si Gao[2,6], Mr. Yu Lei[1], Mr. Xiaopeng Wu[1], Mr. Xudong Pei[2], Prof. Yuefeng Nie[2], Prof. Angus Kirkland[3,4], Dr Peng Wang[1,2]
[1]Department of Physics, University of Warwick, Coventry, UK, [2]National Laboratory of Solid-State Microstructures, Jiangsu Key Laboratory of Artificial Functional Materials, College of Engineering and Applied Sciences and Collaborative Innovation Centre of Advanced Microstructures, Nanjing University, Nanjing, China, [3]The Rosalind Franklin Institute, Harwell Campus, Didcot, UK, [4]Department of Materials, University of Oxford, Oxford, UK, [5]Institute of Materiobiology, College of Science, Shanghai University, Shanghai, China, [6]College of Materials Science and Engineering, Nanjing Tech University, Nanjing, China
558 STEM-EELS unveils atomic stacking in 2D MoSe2 ECM memristors.
Dr Khalil El Hajraoui[1,2], Dr Andrea Capasso[3], Mr Guilherme Araújo[3], Dr Demie Kepaptsoglou[1,2], Prof Quentin. M Ramasse[1,4]
[1]SuperSTEM Laboratory, SciTech Daresbury, Daresbury, United Kingdom, [2]School of Physics, Engineering and Technology, University of York, York, United Kingdom, [3]International Iberian Nanotechnology Laboratory, Braga, Portugal, [4]School of Chemical and Process Engineering & School of Physics and Astronomy, University of Leeds, Leeds, United Kingdom
559 Study of metal powders oxidation by means of Energy Dispersion Spectroscopy (EDS)
Dr. Matteo Giardino[1,2], Dr. Federico Simone Gobber[1,2], Mr. Antonio Pennacchio[1], Prof. Marco Actis Grande[1,2]
[1]Department of Applied Science and Technology (DISAT), Politecnico di Torino, Alessandria, Italy, [2]RU Torino Politecnico, Consorzio INSTM, Firenze, Italy
560 Solid state diffusion as the driving force in the selective oxidation of 2-propanol
Dr. Thomas Götsch[1], Daniel Cruz[1], Patrick Zeller[1,2], Anna Rabe[3,4], Malte Behrens[3,4], Robert Schlögl[1,5], Axel Knop-Gericke[1,5], Thomas Lunkenbein[1]

[1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany, [2]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Berlin, Germany, [3]Christian-Albrechts-Universität zu Kiel, Kiel, Germany, [4]Universität Duisburg-Essen, Essen, Germany, [5]Max Planck Institute for Chemical Energy Conversion, Mülheim a. d. Ruhr, Germany

561 High-resolution investigation of rotavirus VLPs by cryo-EM

Liam Kaylor[1,2], Dr. Sarah McDonald Esstman[3], Dr. Deborah Kelly[2,4]
[1]Molecular, Cellular, and Integrative Biosciences Graduate Program, University Park, United States, [2]Center for Structural Oncology, University Park, United States, [3]Department of Biology, Winston-Salem, United States, [4]Department of Biomedical Engineering, University Park, United States

562 Scale-bridging microscopic characterization of complex energy devices enabled by novel cross-sectional preparation routines

Marco Hepp[1], Charles Ogolla[1], Dominik Stepien[2], Dominik Bresser[2], Benjamin Butz[1], Tristan Zemke[1]
[1]Micro- and Nanoanalytics Group, University of Siegen, Siegen, Germany, [2]Helmholtz Institute Ulm, Ulm, Germany

563 Carbonaceous inclusions from the oldest sediments on Earth

Magnus Harding[1,2], Austin Jarl Boyd[1], Sandra Siljeström[3], Madina Shamsuyeva[4], Pooyan Aliuos[4], Minik Rosing[1], Tue Hassenkam[1]
[1]Globe Institute, University of Copenhagen, Copenhagen, Denmark, [2]Sino-Danish College (SDC), University of Chinese Academy of Sciences, Beijing, China, [3]RISE Research Institutes of Sweden, Stockholm, Sweden, [4]Institute of Plastics and Circular Economy IKK, Leibniz University Hannover, Hannover, Germany

564 Probing Chirality and Topology in Ferrimagnetic Multilayer Systems

Tamer Karaman[1], Daniel Metternich[1,2], Kai Litzius[1], Timo Schmidt[3], Aladin Ullrich[3], Riccardo Battistelli[1,2], Manas Patra[1,2], Manuel Valvidares[4], Daniel Pérez Salinas[4], Jordi Llobet[4], Christopher Klose[5], Michael Schneider[5], Bastian Pfau[5], Andrada-Oana Mandru[6], Reshma Peremadathil Pradeep[6], Konrad Samwer[7], Manfred Albrecht[3], Hans Josef Hug[6], Felix Büttner[1,2]
[1]Experimental Physics V, University of Augsburg, 86159 Augsburg, Germany, Augsburg, Germany, [2]Helmholtz-Zentrum Berlin, 14109 Berlin, Germany, Berlin, Germany, [3]Experimental Physics IV, University of Augsburg, 86159 Augsburg, Germany, Augsburg, Germany, [4]ALBA Synchrotron Light Source, 08290, Barcelona, Spain, Barcelona, Spain, [5]Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, 12489 Berlin, Germany, Berlin, Germany, [6]Empa, Swiss Federal Laboratories for Materials Science and Technology, 8600 Dubendorf, Switzerland, Duebendorf, Switzerland, [7]I. Physics Institute, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany, Goettingen, Germany

565 Multidimensional Electron Ptychography

Mr. Yu Lei[1], Biying Song[2], Zhiyuan Ding[2], Fucai Zhang[3], Xiaoqing Pan[4], Angus Kirkland[5], Dr Peng Wang[1]
[1]Department of Physics, University of Warwick, Coventry, United Kingdom, [2]College of Engineering and Applied Sciences, Nanjing University, Nanjing, China, [3]Department of Electrical and Electronic Engineering, Southern University of Science and Technology,, Shenzhen, China, [4]Department of Chemical Engineering and Materials Science, University of California, Irvine, United States of America, [5]The Rosalind Franklin Institute, Harwell Science and Innovation Campus, Didcot, United Kingdom

566 Simulating electron energy-loss spectroscopy and cathodoluminescence for nanoparticles located on substrates

Alexander Kichigin[1], Mingjian Wu[1], Stefanie Rechberger[1], Benjamin Apeleo Zubiri[1], Maxim Yurkin[2], Erdmann Spiecker[1]
[1]Institute of Micro- and Nanostructure Research (IMN) & Center for Nanoanalysis and Electron Microscopy (CENEM), Friedrich-Alexander-Universität Erlangen-Nürnberg, IZNF, Erlangen, Germany,

[2]CNRS, INSA Rouen Normandie, Univ Rouen Normandie, Normandie Univ, CORIA UMR 6614, Rouen, France

567 Towards Atomic Resolution of Cryogenic Ptychography Single-Particle Analysis (Cryo-EPty SPA)
Mr. Yu Lei[1], Mohammed Yusuf[2], Adrián Pedrazo-Tardajos[2], Judy Kim[2], Julie Staunton[1], Angus Kirkland, Dr Peng Wang[1], Chen Huang[2]
[1] Department of Physics, University of Warwick, Coventry, United Kingdom, [2]The Rosalind Franklin Institute, Harwell Science and Innovation Campus, Didcot, United Kingdom

568 eCHORD crystalline orientation maps: channeling contrast at interfaces
Dr. Hdr Cyril Langlois[1], Dr. Gabriel Denhez L'Hôte[1], M. Thierry Douillard[1], Dr. Matthieu Bugnet[1], Dr. Claire Maurice[2]
[1]INSA Lyon, MATEIS laboratory, Lyon, France, [2]Ecole des Mines Saint-Etienne, LGF laboratory, Saint Etienne, France

569 Coupling Clustering and Channeling Contrast in the Scanning Electron Microscope
Dr. Sudeep Kumar Sahoo[1,2], M. Thierry Douillard[1], Dr. Bianca Frincu[2], Mme Christine Nardin[2], Dr. Hdr Cyril Langlois[1]
[1]INSA Lyon, MATEIS Laboratory, Lyon, France, [2]Constellium Technology Center (C-TEC), , France

570 Water condensation on core-shell nanofibers studied using multiscale environmental electron microscopy
Laura Montes-Montañez[1], Dr Annie Malchère[2], Dr Lucian Roiban[2], Dr Victor Rico[1], Dr Victor Trillaud[2], Prof Philippe Trillaud[2], Prof Karine Masenelli-Varlot[2], Prof Agustín R González-Elipe[1], Dr Ana Borrás[1], Dr Carmen López-Santos[1,3]
[1]Institute of Materials Science of Seville (US-CSIC) , Seville, Spain, [2]INSA Lyon, Universite Claude Bernard Lyon 1, CNRS, MATEIS, UMR5510, Villeurbanne, France, [3]Departamento de Física Aplicada I, Escuela Politécnica Superior, Universidad de Sevilla, Seville, Spain

571 Glacios 2 Cryo-TEM and Smart EPU Software streamline Cryo-EM for drug design with higher throughput
Adrian Koh[1], Michael Adams, Lingbo Yu[1], Fanis Grollios[1], Bart van Knippenberg[1], Abhay Kotecha[1], Basil Greber[2], Oliver Raschdorf[1], Julio Ortiz[3], Edward Pryor[4], Jeffrey Lengyel[4]

618 ACOM-TEM Investigation of the white etching layer formation in rail track

Pr Muriel Véron[1], Matteo Russo[2]

[1]Université Grenoble Alpes, CNRS, Grenoble INP, SIMaP, F-38000 Grenoble, France, [2]Univ. de Lyon, INSA Lyon, CNRS UMR 5510, MATEIS, F-69621 Villeurbanne, France, [3]Univ. de Lyon, INSA Lyon, CNRS UMR 5259 LaMCoS, F-69621 Villeurbanne, France

619 Defect engineering of core-shell systems based on 2D transition metal dichocalgenides

Juan José Quintana González[1], Antonio Jesus Medina Olivera[1], Dr Ramon Manzorro[1], Dr Cédric Pardanaud[2], Dr Rong Sun[1], Dr Ana Belén Hungría[1], Dr Laura Cubillana Aguilera[3], Dr Jose María Palacios Santander[3], Dr Juan Carlos Hernández Garrido[1], Dr Luc Lajaunie[1]
[1]Department of Inorganic Chemistry, Faculty of Sciences. University of Cadiz, Puerto Real, Spain, [2]Aix-Marseille Université, CNRS, PIIM UMR 7345, Marseille, France, [3]Department of Analytical Chemistry, Faculty of Sciences. University of Cadiz,, Puerto Real, Spain

620 Electron energy-gain spectroscopy of optical excitations in integrated photonic structures

Jan-Wilke Henke[1,2], Dr. Yujia Yang[3,4], F. Jasmin Kappert[1,2], Dr. Arslan S. Raja[3,4], Germaine Arend[1,2], Guanhao Huang[3,4], Dr. Armin Feist[1,2], Zheru Qiu[3,4], Rui Ning Wang[3,4], Aleksandr Tusnin[3,4], Dr. Alexey Tikan[3,4], Prof. Dr. Tobias J. Kippenberg[3,4], Prof. Dr. Claus Ropers[1,2]
[1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany, [2]University of Göttingen, 4th Physical Institute, Göttingen, Germany, [3]Institute of Physics, Swiss Federal Institute of Technolog Lausanne (EPFL), Lausanne, Switzerland, [4]Center for Quantum Science and Engineering, Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland

621 Rapid and large FOV mapping of 60° grains in epitaxial MX2 with a segmented detector

Dr. Ankit Nalin Mehta[1], Dr. Gerardo Martinez Alanis[1], Dr. Maxim Korytov[1], Dr. Henry Medina Silva[1], Dr. Paola Favia[1], Dr. Olivier Richard[1], Dr. Eva Grieten[1]
[1]imec, Leuven, Belgium

622 Stability insights of MnO2 electrocatalysts from identical location and in-situ electrochemical liquid cell electron microscopy

Dr. Raquel Aymerich Armengol[1], Lau Morten Kaas[1], Alba Bech Larsen[1], Marika Birkedal Norby[1], Christian Danvad Damsgaard[1,2], Peter Christian Kjærgaard Vesborg[1], Jakob Kibsgaard[1], Stig Helveg[1]
[1]Center for Visualizing Catalytical Processes (VISION), Technical University of Denmark (DTU), Kongens Lyngby, Denmark, [2]Nanolab, Technical University of Denmark (DTU), Kongens Lyngby, Denmark

623 New generation environmental in situ TEM holder for gas cell studies across multiple platforms

Dr. Yevheniy Pivak[1], Dr. Dan Zhou[2], MSc Christian Deen-van-Rossum[1], MSc Ronald Spruit[1], MSc Merijn Pen[1], Dr. Hongyu Sun[1], Dr. Hugo Perez[1]
[1]DENSsolutions BV, Delft, The Netherlands, [2]Leibniz-Institut für Kristallzüchtung (IKZ), Berlin, Germany

624 Cryo lift-out technique to study host-pathogen interaction on cell monolayer

Dr Gautham Hari Narayana Sankara Narayana[1], Sylvie GOUSSARD[1], Guillaume DUMENIL[1], Daria BONAZZI[1]
[1]Institiut Pasteur, Paris, France

625 Revealing atomic structure and composition in ultrahigh energy storage density ferroelectric thin-films

Prof Shery Chang[1,2], Dr Daniel Stroppa[3], Dr Richard Webster[1], Prof Danyang Wang[2]
[1]Electron Microscope Unit, Mark Wainwright Analytical Centre, University of New South Wales, Sydney, Australia, [2]School of Materials Science and Engineering, University of New South Wales, Sydney, Australia, [3]Dectris Ltd, Baden-Daetteil, Switzerland

626 Nanotubes of (SmxY1-x)S-TaS2 based on Quaternary Misfit Layered Compounds (MLCs)

Mr Mohammad Furqan[1,2], Dr Simon Hettler[1,2], Dr MB Sreedhara[3], Dr Reshef Tenne[4], Dr Raul Arenal[1,2,5]

[1]Laboratorio de Microscopias Avanzadas (LMA), Universidad de Zaragoza, Zaragoza, Spain, , ,

627 In situ TEM holder for liquid cell research with combined electrochemical and thermal stimuli control

Dr. Yevheniy Pivak[1], Dr. Hongyu Sun[1], Dr. Vasilis Papadimitriou[1], MSc Christian Deen-van-Rossum[1], Dr. Andres Alvarez[1], MSc Merijn Pen[1], Dr. Joseph Patterson[2], Dr. Hugo Perez[1]
[1]DENSsolutions BV, Delft, The Netherlands, [2]University of California Irvine, Irvine, United States

628 Self-supervised deep learning method for in-cell cryo-electron tomography

Frosina Stojanovska[1,2], Anna Kreshuk[3], Julia Mahamid[1,3], Judith Zaugg[1,4]
[1]Structural and Computational Biology Unit, European Molecular Biology Laboratory, Heidelberg, Germany, [2]Collaboration for Joint PhD Degree between EMBL and Heidelberg University, Heidelberg, Germany, [3]Cell Biology and Biophysics Unit, European Molecular Biology Laboratory, Heidelberg, Germany, [4]Genome Biology Unit, European Molecular Biology Laboratory, Heidelberg, Germany

629 Deep image prior for limited-angle electron tomography

Dr Zineb SAGHI[1], Laure Guetaz[2], Thomas David[2], Philippe Ciuciu[3], Zineb Saghi[1]
[1]Univ. Grenoble Alpes, CEA, Leti, F-38000, Grenoble, France, [2]Univ. Grenoble Alpes, CEA, Liten, F-38000, Grenoble, France, [3]Univ. Paris Saclay, CEA-NeuroSpin, INRIA, Parietal, Gif-sur-Yvette, France

630 Characterisation of red fluorescent protein FLIM properties and comparison with novel StayGold live cell imaging

Dr. Philipp Tripal[1], MSc Hanan Said[2], Dr. Benjamin Schmid[1], Dr. Ralph Palmisano[1]
[1]Optical Imaging Competence Centre, Friedrich-Alexander Universität, Erlangen, Germany, [2]University of Applied Science, Coburg, Germany

631 Preparation of biological samples for cryo-electron microscopy using the HPF "Waffle" method

Mrs. Jana Moravcová[1], Petra Reznickova[2], Martin Polak[1], Jiri Novacek[1]
[1]Masaryk University, Central European Institute of Technology, Brno, Czech Republic, [2]Thermo Fisher Scientific, Brno, Czech Republic

632 Elemental segregation at substrate/metal interface to manipulate heterogeneous nucleation

Dr Shihao Wang[1,2,3], Dr Yun Wang[3], Dr Zhongyun Fan[3], Dr Quentin Ramasse[1,2]
[1]SuperSTEM Laboratory, STFC Daresbury Campus, Daresbury WA4 4AD, United Kingdom, [2]School of Chemical and Process Engineering, University of Leeds, Leeds LS2 9J, United Kingdom, [3]BCAST, Brunel University London, Uxbridge, Middlesex UB8 3PH, United Kingdom

633 Consistency and reliability of ptychographic deconvolution approaches

Tizian Lorenzen[1], Dr. Benedikt Diederichs[1,2], Charles Ogolla[3], Prof. Benjamin Butz[3], Prof. Knut Müller-Caspary[1]
[1]Ludwig-Maximilians-Universität, Munich, Germany, [2]Institute of Biological and Medical Imaging, Helmholtz Zentrum Munich, Neuherberg, Germany, [3]Micro- and Nanoanalytics Group, University of Siegen, Siegen, Germany

634 Atomic-resolution mapping of phonon modes across Magnéli structures in thermoelectric (Al,Nb)-doped TiO2

Dr Shihao Wang[1,2], Dr Demie Kepaptsoglou[1,3], Dr Jan Rusz[4], Dr Paul Zeiger[4], Dr Xiaodong Liu[5,6], Dr Robert Freer[6], Dr Quentin Ramasse[1,2]
[1]SuperSTEM Laboratory, STFC Daresbury Campus, Daresbury WA4 4AD, United Kingdom, [2]School of Chemical and Process Engineering, University of Leeds, Leeds LS2 9JT, United Kingdom, [3]Department of Physics, University of York, York Yo10 5DD, United Kingdom, [4]Department of Physics and Astronomy, University of Uppsala, P.O. Box 516, 75120, Uppsala, Sweden, [5]Department of

Mechanical, Materials & Aerospace Engineering, University of Liverpool, Liverpool L69 3BX, United Kingdom, [6]Department of Materials, University of Manchester, Manchester M13 9PL, United Kingdom

635 Innovative Designs For Enhancing the Functionality of MEMS-Based Phase Plates through Numerical Simulation and Optimisation

Mr Payam Habibzadeh Kavkani[1,2], Dr Vincenzo Grillo[2], Professor Marco Beleggia[1]
[1]Universitá di Modena e Reggio Emilia, Modena, Italy, [2]CNRNANO - Istituto di Nanoscienze - Centro S3, Modena, Italy

636 Enhanced nanoscale phase characterisation in modern steels using precession electron diffraction and energy filtering

Aleksander Brozyniak[1], Matthias Wallner[2], Philipp Kürnsteiner[1], Peter Oberhumer[1], Katharina Steineder[2], Heiko Groiss[1]
[1]Christian Doppler Laboratory for Nanoscale Phase Transformations, Center for Surface and Nanoanalytics, Johannes Kepler University Linz, Altenberger Str. 69, 4040 Linz, Austria, [2]voestalpine Stahl GmbH, voestalpine-Straße 3, 4020 Linz, Austria

637 Accessible low-cost, open-source, single-shot phase imaging implemented on an openFrame-based microscope

Huihui Liu[1], Sunil Kumar[1,2], Edwin A Garcia Castano[1], Yasin Razak[3], William Flanagan[1], Jonathan Lightley[1], Ruiyang D Duan[1], Freen Liao[1], Xiaoyu Sun[1], Shanhe N Zeng[1], Brian D Robertson[4], Christopher W Dunsby[1,2], Paul (PHOT) M W French[1,2]
[1]Physics Department, Imperial College London, SW7 2AZ, London, United Kingdom, [2]Francis Crick Institute, 1 Midland Road, NW1 1AT, London, United Kingdom, [3]University of Cape Town, , South Africa, [4]Department of Life Sciences, Imperial College London, SW7 2AZ, , United Kingdom

638 Beyond Ribosomes: In Situ Structural Biology of Diverse Targets in C. reinhardtii

Dr Ron Kelley[1], Dr Xianjun Zhang[1], Dr. Martin Obr[1], Mr. Sagar Khavnekar[1], Dr Jessica Heebner[1], Dr Saikat Chakraborty[1], Dr Ricardo Righetto[2], Dr Florent Waltz[2], Dr Alicia Michael[2], Dr Wojciech Wietrzynski[2], Dr Grigory Tagiltsev[3], Prof John Briggs[3], Prof Juergen Plitzko[3], Dr Ben Engel[2], Dr. Abhay Kotecha[1]
[1]Thermo Fisher Scientific, Eindhoven, Netherlands, [2]Biozentrum, University of Basel, Basel, Switzerland, [3]Department of Molecular Structural Biology, Max Planck Institute of Biochemistry, Martinsried, Germany

639 Quantitative analysis of single-atom support interactions by Deep Learning techniques

Paula Aniceto Ocaña[1], José Marqueses Rodríguez[1], José Antonio Pérez Omil[1], José Juan Calvino[1], Carmen Esther Castillo[1], Miguel López Haro[1]
[1]Departamento de Ciencias de los Materiales e Ingeniería Metalúrgica y Química Inorgánica. Facultad de Ciencias, Campus Rio San Pedro S/N. Puerto Real. 11510. Cádiz, Spain

640 Probing photonic resonant modes in InAs semiconductor nanostructures by STEM-EELS

Yajie Wang[1], Qingnan Cai[1], Zifan Huo[2], Yanhui Zhang[2], Pingping Chen[2], Kun Ding[1], Changlin Zheng[1]
[1]State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai, China, [2]State Key Laboratory of Infrared Physics, Shanghai Institute of Technology Physics，Chinese Academy of Sciences, Shanghai, China

641 Application of cryogenic in situ biasing (S)TEM holder to study phase transitions in complex oxides

Dr. Yevheniy Pivak[1], PhD Vasilis Papadimitriou[1], MSc Tianshu Jiang[2], PhD Vladimir Roddatis[3], PhD Leopoldo Molina-Luna[2], PhD Michele Conroy[4]
[1]DENSsolutions, Delft, The Netherlands, [2]TU Darmstadt, Darmstadt, Germany, [3]GFZ German Research Center for Geosciences, Potsdam , Germany, [4]Imperial College London, London, United Kingdom

642 Multiscale study of water condensation on aerosols using in-situ Environmental Scanning and Transmission Electron Microscopies
Dr Eric Ehret[1], Dr Louis-Marie Lebas[2], Dr Annie Malchère[2], Dr Joseph Vas[3], Dr Francisco Cadete Santos Aires[1], Dr Lucian Roiban[2], Dr Martial Duchamp[3], Prof Karine Masenelli-Varlot[1], Dr Thierry Epicier[1]
[1]Universite Claude Bernard Lyon 1, CNRS, IRCELYON, UMR 5256, Villeurbanne, France, [2]INSA Lyon, Universite Claude Bernard Lyon 1, CNRS, MATEIS, UMR5510, Villeurbanne, France, [3]3MajuLab, International Joint Research Unit IRL 3654, CNRS, Université Côte d'Azur, Sorbonne Université, National University of Singapore, Nanyang Technological University, Singapore, Singapore
643 In- and ex-situ implantation of helium to characterise faults in titanium beryllide
Dr Jo Sharp[1], Dr Slava Kuksenko[2], Dr Ramil Gaisin[3], Professor Jonathan Hinks[1], Dr Graeme Greaves[1], Professor Stephen Donnelly[1], Professor Pavel Vladimirov[3]
[1]University of Huddersfield, Huddersfield, United Kingdom, [2]UKAEA, Culham, United Kingdom, [3]Karlsruhe Institute of Technology, Karlsruhe, Germany
644 Scale-Bridging Analysis of Hierarchical Mesoporous Transition Metal Foams
Jonas Frohne[1], Dr.-Ing. Julian Müller[1], Dr. Jean Marie Vianney Nsanzimana[1], Charles Otieno Ogolla[1], Prof. Benjamin Butz[1]
[1]Micro- and Nanoanalytics Group/University of Siegen, Siegen, Germany
645 Intralayer modification on Ti3C2Tz MXene Multilayer by Tailoring Surface Terminations
Mr Hari Hara Sudhan Thangavelu[1], Assoc. Prof. Fredrik Eriksson[1], Asst. Prof. Leiqiang Qin[2], Assoc. Prof. Jonas Björk[2], Prof. Johanna Rosén[2], Prof. Per Persson[1]
[1]Thin Film Physics Division, Department of Physics, Chemistry and Biology (IFM), Linköping University, SE - 58183, Sweden, [2]Materials Design Division, Department of Physics, Chemistry, and Biology (IFM), Linköping University, SE - 58183, Sweden
646 Analytical Phase-Shifting Electron Holography using Fresnel-corrected holograms
Augustin Nogier[1], Aurélien Masseboeuf[1], Kévin Garello[1]
[1]SPINTEC, Grenoble, France
647 Effects of electron cascade and lamella preparation on InGaN quantum well recombination dynamics
Nika van Nielen[1], Delphine Lagard[2], Cleo Santini[3], Florian Castioni[4], Robin Cours[3], Andrea Balocchi[2], Teresa Hungria[5], Andrey Tsatsulnikov[6], Alexei Sakharov[6], Andrey Nikolaiev[6], Nikolay Cherkashin[3], Luiz Tizei[4], Albert Polman[1], Sophie Meuret[3]

665 Ptychography Optimization for Atomic Analysis of Bending Mode in Bilayer Transition Metal Dichalcogenide Translational Motion

Yunyeong Chang[1], Dr Jinseok Ryu[3], Prof Hyobin Yoo[2], Prof Heung Nam Han[1], Prof Miyoung Kim[1]
[1]Seoul National University, , Republic of Korea, [2]Sogang University, , Republic of Korea, [3]Diamond Light Source Ltd, , United Kingdom

666 Comparative Analysis of Self-Supervised Learning Techniques for Electron Microscopy Images

Dr.-ing. Bashir Kazimi[1], Prof. Dr. Stefan Sandfeld[1,2]

[1]Forschungszentrum Jülich, Institute for Advanced Simulation – Materials Data Science and Informatics (IAS-9), Aachen, Germany, [2]RWTH Aachen University, Chair of Materials Data Science and Informatics, Aachen, Germany

667 EDX-based annotation of biological features in large-scale EM

Peter Duinkerken[1], Dr. Ahmad Alsahaf[1], Dr. Jacob Hoogenboom[2], Dr. Ben Giepmans[1]
[1]Department of Biomedical Sciences, University Groningen, University Medical Center Groningen, Groningen, the Netherlands, [2]Department of Imaging Physics, Delft University of Technology, Delft, the Netherlands

668 Improving segmentation of FIB tomography data

Dr.-Ing. Martin Ritter[1], M.sc. Trushal Sardhara[2], Prof. Dr. med. Roland Aydin[2], Prof. Dr.-Ing. Christian Cyron[2]
[1]Electron Microscopy Unit, Hamburg University of Technology, Hamburg, Germany, [2]Institute for Continuum and Material Mechanics, Hamburg University of Technology, Hamburg, Germany

669 Phase formation pathways of Me2+ oxides on sapphire (α-Al2O3) substrates

M.Sc. Yasemin Akyol[1], Dr. Sorour Semsari Parapari[2], Prof. Sašo Šturm[2], Prof. Cleva W. Ow-Yang[1,3], Prof. Mehmet Ali Gulgun[1,3]
[1]Materials Science and Nano Engineering, Sabanci University, Tuzla, Istanbul, Turkey, [2]Department for Nanostructured Materials, Jožef Stefan Institute, Jamova Cesta 39, Ljubljana, Slovenia, [3]Sabanci University Nanotechnology Application Center (SUNUM), Tuzla, Istanbul, Turkey

670 A new transgenic mouse model for functional tracing of circulation via albumin-tagged fluorescent probes

Xiaowen Wang[1], Marta Vittani[1], Ashley Bomin Lee[1], Yuichi Hiraoka[2], Ayumu Konno[3,5], Philip Knak[1], Peter Kusk[1], Masaki Nagao[1], Miho Terunuma[4], Hirokazu Hirai[3,5], Maiken Nedergaard[1,6], Kohichi Tanaka[2], Hajime Hirase[1,6]
[1]Center for Translational Neuromedicine, University of Copenhagen, Copenhagen, Denmark, [2]Laboratory of Molecular Neuroscience, Medical Research Institute (MRI), Tokyo Medical and Dental University (TMDU), Tokyo, Japan, [3]Department of Neurophysiology and Neural Repair, Gunma University Graduate School of Medicine, Maebashi, Japan, [4]Division of Oral Biochemistry, Faculty of Dentistry & Graduate School of Medical and Dental Sciences, Niigata University, Niigata, Japan, [5]Viral Vector Core, Gunma University Initiative for Advanced Research, Maebashi, Japan, [6]Center for Translational Neuromedicine, University of Rochester Medical Center, Rochester, USA

671 Influence of low-pressure atmosphere in the pores formed in hexagonal boron nitride under electron irradiation

Umair Javed[1,2], Clara Kofler[1,2], Clemens Mangler[1], Jani Kotakoski[1]
[1]University of Vienna, Faculty of Physics, Vienna, Austria, [2]University of Vienna, Vienna Doctoral School in Physics, Vienna, Austria

672 Unsupervised Machine Learning-based STEM diffraction pattern denoising for enhanced grain visualization in phase change materials

Karina Ruzaeva[1], Dr. Dieter Weber[2], Jonas Werner[3], Prof. Stefan Sandfeld[1]
[1]IAS-9, Forschungszentrum Jülich, Jülich, Germany, [2]ERC-1, Forschungszentrum Jülich, Jülich, Germany, [3]GFE, RWTH Aachen University, Aachen, Germany

673 Investigation of Production of Boron Nanotubes by Ultrasonication

Dr. Ahmet Eymen Aksener[1], Prof.Dr. Mehmet Ali Gülgün[2], Dr. Selçuk Birdoğan[1]
[1]Sabancı University Nanotechnology Research and Application Center, Istanbul, Turkey, [2]Sabancı University, Faculty of Engineering and Natural Sciences, Istanbul, Turkey

674 On how to tame the beast: Towards a high-throughput plasma FIB pipeline

Elisa Lisicki[1,2,3], Dr. Tatjana Taubitz[1,3], Prof. Dr. Stefan Raunser[1], Dr. Sebastian Tacke[1]

[1]Department of Structural Biochemistry, Max Planck Institute of Molecular Physiology, Dortmund, Germany, [2]International Max Planck Research School for Living Matter, Dortmund, Germany, [3]These authors contributed equally, ,

675 Imaging the three-dimensional morphology of granular superconductors with energy-filtered TEM tomography

Lucas Brauch[1,4], Dr. Di Wang[2,3], Dr. Thomas Reisinger[1], Prof. Dr. Christian Kübel[2,3,4], Prof. Dr. Ioan Pop[1]
[1]Karlsruhe Institute of Technology, Institute for Quantum Materials and Technologies, Eggenstein-Leopoldshafen, Germany, [2]Karlsruhe Institute of Technology, Institute of Nanotechnology, Eggenstein-Leopoldshafen, Germany, [3]Karlsruhe Institute of Technology, Karlsruhe Nano Micro Facility, Eggenstein-Leopoldshafen, Germany, [4]Technical University of Darmstadt, Institute of Materials Science, Darmstadt, Germany

676 Nanodiamond-based quantum sensing of mechanoregulated metabolic plasticity of cardiac fibroblasts

Dr Aldona Mzyk[1], MSc Ezgi Yilmaz[1], MSc Arthur Dervillez[1], Dr Agostina Crotta Asis[2], Prof. Giovanni D'Angelo[2], Prof. Kirstine Berg-Sørensen[1]
[1]Technical University of Denmark, Kongens Lyngby, Denmark, [2]École Polytechnique Fédérale de Lausanne, , Switzerland

677 FIB-SEM and automatic segmentation for investigation of mitochondrial organization in cells of urinary bladder urothelium

Samo Hudoklin[1], Bruno Humbel[2], Manca Žerovnik Mekuč[3], Ciril Bohak[3], Matija Marolt[3], Rok Romih[1]
[1]Institute of Cell Biology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [2]Electron Microscopy Facility, University of Lausanne , Lausanne, Swizerland, [3]Faculty of Computer and Information Science, University of Ljubljana, Ljubljana, Slovenia

678 Investigating microstructural phenomena in Additive Manufactured metals through high temporal thermal cycles in-situ heating

Dr. Alice Bastos da Silva Fanta[1], Yi-Chieh Yang[1], Christina Koenig[1], Prof. Joerg Ralf Jinschek[1]
[1]DTU Nanolab, Kgs. Lyngby, Denmark

679 The effects of solution processing methods on halide perovskite nanostructure

Dr Alexandra Sheader[1], Dr Ryley Ratnasingham[2], Dr Nakita Noel[1]
[1]University of Oxford, Oxford, UK, [2]Eindhoven University of Technology TU/e, Eindhoven, Netherlands

680 Multimodality and correlative low-voltage electron microscopy: powerful tool for imaging in life and material sciences

Mgr. Jan Dobeš[1], Jaromír Bačovský[1], Radka Martínková[1], Jan Vysloužil[2], Zuzana Bytešníková[3]
[1]Delong Instruments, Brno, Czech Republic, [2]Pragolab, Brno, Czech Republic, [3]Department of Chemistry and Biochemistry, Mendel University, Brno, Czech Republic

681 Mean inner potential change of latex sphere with temperature measured using off-axis electron holography

Dr. Yan Lu[1], Peng-Han Lu[1], Dominik Biscette[2], Denys Sutter[2], Prof. Giulio Pozzi[3], Prof. Rafal E. Dunin-Borkowski[1]
[1]Forschungszentrum Juelich, Juelich, Germany, [2]CondenZero AG, Zurich, Switzerland, [3]University of Modena and Reggio Emilia, Modena, Italy

682 Shedding light on the birth of hybrid perovskites by In-Situ TEM and Synchrotron X-ray scattering

Dr Charles Sidhoum[1,2], Dr Doru Constantin[3], Dr Dris Ihiawakrim[1], Dr Marc Lenertz[1], Dr Thomas Bizien[4], Prof. Clément Sanchez[2,5], Prof. Ovidiu Ersen[1]

[1]Collège de France, Paris, France, [2]Institut de Physique et Chimie des Matériaux de Strasbourg, Strasbourg, France, [3]Institut Charles Sadron, Strasbourg, France, [4]Synchrotron SOLEIL, Saint Aubin, France, [5]Laboratoire de Chimie de la Matière Condensée de Paris, , France

683 Ptychography at finite dose in SrTiO3

Dr Malcolm Dearg[1], Mr James Gilbert[1], Mr Nick Michaelides[1], Dr Laura Clark[1]
[1]School of Physics, Engineering and Technology; University of York, York, United Kingdom

684 Reactivity of High Entropy Nanoalloys under O2 and CO Oxidation reaction studied by in-situ TEM

Syrine Krouna[1], Jaysen Nelayah[1], Christian Ricolleau[1], Guillaume Wang[1], Hakim Amara[2], Damien Alloyeau[1]
[1]Université Paris Cité, Paris, France, [2]ONERA, Châtillon , France

685 Attosecond electron microscopy using free-electron homodyne detection

John Gaida[1,2], Hugo Lourenço-Martins[1,2], Murat Sivis[1,2], Thomas Rittmann[1,2], Armin Feist[1,2], F. Javier García de Abajo[3,4], Claus Ropers[1,2]

706 3D Operando Monitoring of lithiation spatial composition in NMC-cathode electrode by X-ray nano-CT & XANES-techniques
Dr. Arnaud Demortière[1], Dr. Tuan-Tu Nguyen[1], Dr. Vincent De Andrade[2], Dr. Zeliang Su[1]
[1]Laboratoire de Réactivité et Chimie des Solides (LRCS), CNRS UMR7314, Amiens , France, [2]Argonne NL, Chicago, USA
707 Coherent inelastic scattering probed by holographic scanning transmission electron microscopy
Dr. Nora Bach[1], Tim N. Dauwe[1], Dr. Murat Sivis[1], Prof. Dr. Claus Ropers[1]
[1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany
708 Improving electron tomography of mesoporous silica structures by Ga intrusion
Thomas Przybilla[1], Johannes Böhmer[1], Alexander Kichigin[1], Moritz Buwen[1], Alexander Götz[1], Dominik Drobek[1], Jakob Söllner[2], Matthias Thommes[2], Benjamin Apeleo Zubiri[1], Erdmann Spiecker[1]
[1]Institute of Micro- and Nanostructure Research (IMN) & Center for Nanoanalysis and Electron Microscopy (CENEM), Department of Materials Science and Engineering, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [2]Institute of Separation Science and Technology, Department of Chemical and Biological Engineering, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany
709 The significance of the phonon polarization vector in vibrational EELS
Paul Zeiger[1], Jan Rusz[1]
[1]Uppsala University, Uppsala, Sweden
710 Direct imaging of deformation in metallic glasses using precession nanodiffraction mapping
Dipl.-Ing. Simon Fellner[1], Dipl. Ing. Lukas Schretter[1], Univ. Prof. Dr.-Ing. Habil. Dr. h.c. Jürgen Eckert[1,2], Dr. Christoph Gammer[1]
[1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Leoben, Austria, [2]Department of Materials Science, Montanuniversität Leoben, Leoben, Austria
711 Unveiling moiré-induced topological polar structures in freestanding ferroelectric membranes
Dr Gabriel Sanchez Santolino[1], Victor Rouco[1], Sergio Puebla[2], Hugo Aramberri[3], Victor Zamora[1], Fabian Cuellar[1], Carmen Munuera[2,4], Federico Monpean[2,4], Mar García-Hernandez[2,4], Andrés Castellanos-Gomez[2,4], Jorge Íñiguez[3,5], Carlos León[1,4], Jacobo Santamaría[1,4]
[1]GFMC. Dept. Fisica de Materiales. Facultad de Fisica. Universidad Complutense. 28040 Madrid, Spain, , , [2]Instituto de Ciencia de Materiales de Madrid ICMM-CSIC 28049 Cantoblanco. 712 Oxygen vacancy imaging in complex oxides by a 4D-STEM optimized virtual detector

Francisco Fernandez Canizares[1,2], PhD. Student Isabel Tenreiro[1], Dr. Hamish Brown[3], Dr. Juan Ignacio Beltran Finez[1], Prof. Alberto Rivera Calzada[1], Prof. Maria Varela[1,2], Dr. Gabriel Sanchez-Santolino[1,2]
[1]Department of Materials Physics, Universidad Complutense de Madrid, Madrid, Spain, [2]Instituto Pluridisciplinar, Universidad Complutense de Madrid, Madrid, Spain, [3]Ian Holmes Imaging Center | Bio21 Molecular Science & Biotechnology Institute, Parkville, Australia

713 Correlative cryo soft x-ray tomography and fluorescent microscopy of biological samples in the laboratory

Mr Kenneth Fahy[1], Dr. Sergey Kapishnikov[1], Dr. Paul Sheridan[1], Mr. William Fyans[1], Dr. Fergal O'Reilly[1,2,3], Mr. Tony McEnroe[1]
[1]SiriusXT, Dublin, Ireland, [2]UCD School of Physics, Dublin 4, Ireland , [3]UCD School of Biology and Environmental Science, Dublin 4, Ireland

714 Understanding the effect of Al:ZnO coating on the structural and chemical stabilities of LiNi1/3Mn1/3Co1/3O2 electrode

Ardavan Makvandi[1,5], Dr. Michael Wolff[2], Dr. Sandra Lobe[2], Bastian Heidrich[3], Dr. Martin Peterlechner[1,5], Dr. Christoph Gammer[4], Dr. Sven Uhlenbruck[2], Prof. Martin Winter[3,6], Prof. Gerhard Wilde[1]
[1]Institute of Materials Physics, University of Münster, Münster , Germany, [2]Forschungszentrum Jülich GmbH, Institute of Energy and Climate Research, Materials Synthesis and Processing (IEK-1) Jülich Aachen Research Alliance: JARA-Energy, Jülich, Germany, [3]MEET Battery Research Center, Institute of Physical Chemistry, University of Münster, Münster , Germany, [4]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Leoben, Austria, [5]Laboratory for Electron Microscopy, Karlsruhe Institute of Technology, Karlsruhe, Germany, [6]Helmholtz Institute Münster, IEK-12 Forschungszentrum Jülich GmbH, Münster , Germany

715 Momentum-resolved STEM Tomography of Gold-Silver core-shell Nanoparticles

Sebastian Sturm[1], Dr. Felizitas Kirner[2], Prof. Dr. Elena Sturm[2], Prof. Dr. Knut Müller-Caspary[1]
[1]Ludwig-Maximilians-Universität München, Department of Chemistry, Munich, Germany, [2]Ludwig-Maximilians-Universität München, Department of Earth and Environmental Sciences, Munich, Germany

716 Phase Stability and Evolution of Defect Structure in (CoCuMgNiZn)-Entropy Stabilized Oxide

Mr. Saptarshi Mukherjee[1], Professor Nilay Krishna Mukhopadhyay[1], Dr. Joysurya Basu[1]
[1]Department of Metallurgical Engineering, Indian Institute of Technology (BHU), Varanasi, Varanasi, India

717 The study of spatial relationship between Restrictor complex and RNA-Pol II through Expansion Microscopy

Dr Simona Rodighiero[1], Dr Marta Russo[1], Dr Mattia Marenda[1], Carolina Borriero[1], Dr Danilo Polizzese[1], Dr Gioacchino Natoli[1]
[1]Department of Experimental Oncology, European Institute of Oncology, Milan, Italy

718 Developing cryo-Volume Electron Microscopy using the JEOL 4700 cryo-FIBSEM to address biological ultrastructural questions

Ms Maryna Kobylynska[1], Professor Pippa Hawes[1], Professor Roland Fleck[1]
[1]King's College London, London, United Kingdom

719 Femtosecond extreme-ultraviolet imaging of magnetic domains during ultrafast demagnetization

Dr. Hung-Tzu Chang[1], Sergey Zayko[1], Timo Schmidt[2], Murat Sivis[1,3], Manfred Albrecht[2], Claus Ropers[1,3]
[1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany, [2]Experimental Physics IV, University of Augsburg, Augsburg, Germany, [3]4th Physical Institute, University of Göttingen, Göttingen, Germany

720 Evaluation of SXES on different kind of materials : successes and failures

Jean-Louis Longuet[1]
[1]CEA Le Ripault, Monts, France
721 Nanowire Triple-Junction GaInP/InP/InAsP Solar Cells Realized
Prof. Reine Wallenberg[1,2], Dr Lukas Hrachowina[2], Prof Magnus Borgström[2]
[1]national center for HREM, Lund University, Lund, Sweden, [2]NanoLund, Lund University, Lund, Sweden
722 Machine Learning-Enabled 3D Visualization for Microstructural Risk Assessment in Creep Strength Enhanced Ferritic (CSEF) Steels
Dr. Xiyu Zhang[1], Dr. Mark Jepson[1], Dr. Simon Hogg[1], Dr. Stuart Robertson
[1]Loughborough University, Loughborough, United Kingdom
723 Single-Layer Transition Metal Dichalcogenides: Unveiling Excitonic Processes with Multimodal Microscopy
Dr Herman Duim[1], Dr Noémie Bonnet[1], Jassem Baaboura[2], Dr Florian Castioni[2], Dr Steffi Y. Woo[2], Ching-Hwa Ho[3], Kenji Watanabe[4], Takashi Taniguchi[5], Dr Luiz H.G. Tizei[2], Dr Toon Coenen[1]
[1]Delmic, Delft, The Netherlands, [2]Laboratoire de Physique des Solides, Université Paris-Saclay, Centre National de la Recherche Scientifique, Orsay, France, [3]Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan, [4]Research Center for Electronic and Optical Materials, National Institute for Material Science, Tsukuba, Japan, [5]Research Center for Materials Nanoarchitechtonics, National Institute for Material Science, Tsukuba, Japan
724 Atomic Resolved In situ mechanical Microscopy leads to realize the negative mixing enthalpy solid solutions
Dr. Zibing An[1], Dr. Ang Li[2], Prof. Shengcheng Mao[2], Dr. Wei Li[2], Prof. Lihua Wang[2], Prof. Xiaodong Han[1]
[1]Southern University of Science and Technology, Shenzhen, China, [2]Beijing University of Technology, Beijing, China
725 Ultra-fast and facile synthesis of cathodes for rechargeable batteries using an organic syntehsis route
Dr Saul Rubio[2], Mr Julio E. de la Rosa-Melian[1], Dr Francisco J. Garcia-Garcia[1], Dr Eva M. Perez-Soriano[1], Dr Cristina Arevalo[1], Dr Isabel Montealegre-Melendez, Dr Ana M Beltrán[2], Dr Juan G. Lozano[1]
[1]Departamento de Ingeniería y Ciencia de los Materiales y del Transporte, Escuela Técnica Superior de Ingeniería, Universidad De Sevilla, Sevilla, Spain, [2]Departamento de Ingeniería y Ciencia de los Materiales y del Transporte, Escuela Politécnica Superior, Universidad De Sevilla, Sevilla, Spain
726 Evaluating spherical models of EBSD patterns for forward modelling indexing
Dr René De Kloe[1], William Lenthe[2], Stuart Wright[2], Matt Nowell[2]
[1]EDAX-Gatan, Tilburg, The Netherlands, [2]EDAX-Gatan, Pleasanton, USA
727 The role of atomic displacements in high-resolution scanning transmission electron microscopy imaging of strained nanoparticles
Prof. Dr Roland Kröger[1], Dr Shuayl Alotaibi[1]
[1]University of York, York, United Kingdom
728 Unravelling the collagen mineralization using multiscale in situ X-ray-scattering/Raman spectroscopy and ex situ electron microscopy/nano-Xray-fluorescence
Prof. Dr Roland Kröger[1], Dr Julia Parker[2], Ms Emma Tong[1]
[1]University of York, York, United Kingdom, [2]Diamond Light Source, Harwell, United Kingdom
729 Visualization of binder mixtures in hard carbon composite electrodes using OsO4 and uranyl acetate staining
Gregor Neusser[1], Tom Philipp[1], Sven Daboss[1], Clarissa Read[2,3], Paul Walther[2], Christine Kranz[1]

[1]Institute of Analytical and Bioanalytical Chemistry, Ulm University, Ulm, Germany, [2]Central Facility for Electron Microscopy, Ulm University, Ulm, Germany, [3]Institute of Virology, Ulm University Medical Center, Ulm, Germany

730 Analysis of molecular packing and nanoscale atomic variation in polymer semiconductors

Sang Pham[1], Sean Collins[1,2]
[1]Bragg Centre for Materials Research & School of Chemical and Process Engineering, University of Leeds, Leeds, United Kingdom, [2]School of Chemistry, University of Leeds, Leeds, United Kingdom

731 Toward 3D imaging of the PEMFC electrode microstructure

Dr Laure GUETAZ[1], Mr Mamadou Sangare[1], Dr Thomas David[1], Dr Zineb Saghi[2], Dr Arnaud Morin[1], Dr Joël Pauchet[1]
[1]Université Grenoble Alpes, CEA, LITEN, Grenoble, France, [2]Université Grenoble Alpes, CEA, LETI, Grenoble, France

732 Correlating atomic-resolution structure to the properties of transition metal nitride coatings

Dr. Zaoli Zhang[1], Dr. Zhuo Chen[1], Mr. Yong Huang[1]
[1]Erich Schmid Institute, Austrian Academy of Sciences, Leoben, Austria

733 Cross-sectioning of adherent cells on thin plastic substrate for serial block-face imaging

Anne Kauter[1], Silvio Bürge[1], Christian Klotz[2], Michael Laue[1]
[1]Advanced Light and Electron Microscopy (ZBS 4), Centre for Biological Threats and Special Pathogens, Robert Koch Institute, Berlin, Germany, [2]Mycotic and Parasitic Agents and Mycobacteria (FG16), Department of Infectious Diseases, Robert Koch Institute, Berlin, Germany

734 Direct visualization of chemical transport in solid-state chemical reactions by time-of-flight secondary ion mass spectrometry

Sang Pham[1], Sean Collins[1,2]
[1]Bragg Centre for Materials Research & School of Chemical and Process Engineering, University of Leeds, Leeds, United Kingdom, [2]School of Chemistry, University of Leeds, Leeds, United Kingdom

735 HRSTEM study on the phase formations and transitions in nanolaminated MAB phases

Sebastian Lellig[1,2], Peter Pöllmann[1], Dr. Peter Schweizer[2], Dr. Dimitri Bogdanovski[1], Amir Hossein Navidi Kashani[1], Dr. Marcus Hans[1], Dr. Clio Azina[1], Dr. Soheil Karimi Aghda[1], Dr. Damian M. Holzapfel[1], Paula Zöll[1], Dr. Szilárd Kolozsvári[4], Dr. Peter Polcik[4], Professor Dr. Daniel Primetzhofer[3], Professor Dr. Johann Michler[2], Professor Dr. h.c. Jochen M. Schneider[1,5]
[1]Materials Chemistry, RWTH Aachen University, Aachen, Germany, [2]Laboratory for Mechanics of Materials and Nanostructures, empa, Thun, Switzerland, [3]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden, [4]Plansee Composite Materials GmbH, Lechbruck am See, Germany, [5]Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany

736 Mechanics of morphogenesis – The re-invention of cell sheet folding

Dr. Pierre Haas[1,2,3], Dr Steph Höhn[4]
[1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany, [3]Center for Systems Biology Dresden, Dresden, Germany, [4]Department of Applied Mathematics and Theoretical Physics, Cambridge, United Kingdom

737 Investigating solar degradation mechanisms of the Ta3N5 photoelectrode by in-situ transmission electron microscopy

Dr. Annett Thøgersen[1], Dr. Øystein Dahl[4], Dr. Shima Kadkhodazadeh[2], Dr. Michael Seifner[2], Msc. Martin Fleissner Sunding[1], Dr. Ingeborg-Helene Svenum[4], Dr. Mathieu Grandcolas[1], Professor Thomas Willum Hansen[2], Dr. Ingvild Julie Thue Jensen[1], Dr. Athanasios Chatzitakis[3]
[1]SINTEF, Oslo, Norway, [2]DTU, Lyngby, Denmark, [3]UiO, Oslo, Norway, [4]SINTEF, Trondheim, Norway

738 Band gap measurements of aluminum and indium doped Ga2O3 multilayers

Dr. Annett Thøgersen[1], Professor Lasse Vines[2], Dr. Georg Muntingh[1], Professor Øystein Prytz[2], Professor Holger von Wenckstern[3], Dr. Ingvild Julie Thue Jensen[1]
[1]SINTEF, Oslo, Norway, [2]UiO, Oslo, Norway, [3]University of Leipzig, Leipzig, Germany

739 The fatigue response of the IN939 superalloy prepared by additive manufacturing

Ivo Kuběna[1], Markéta Gálíková[1], Ivo Šulák[1]
[1]Institute of Physics of Materials, Czech Academy of Sciences, Brno, Czech Republic

740 Revealing the vacancy ordering in Prussian blue analogues through serial electron diffraction

Mr Shihui Feng[1], Dr Hanna Boström[1], Dr Cheuk-Wai Tai[1]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden

741 Characterization of 2DEG on WG semiconductors through sub-sampled 4DSTEM

Dr Giuseppe Nicotra[1], Dr Gianfranco Sfuncia[1], Dr Alex Robinson W[2], Dr Daniel Nicholls[3], Mr Jack Wells[2,3], Dr Antonio Mio M[1], Mr Corrado Bongiorno[1], Dr Cettina Bottari[5], Dr Salvatore Adamo[5], Dr Alfio Russo[5], Dr Santi Alessandrino[5], Prof. Nigel Browning D[4], Dr Corrado Spinella[1]
[1]CNR-IMM zona industriale strada VIII n.5, Catania, Italia, [2]SenseAI Innovations Ltd, Liverpool, UK, [3]Distributed Algorithms Centre for Doctoral Training, Liverpool, UK, [4]University of Liverpool, Liverpool, UK, [5]STMicroelectronics, Catania, Italy

742 Scanning precession electron diffraction tilt series for orientation analysis

Prof. Dr. Ir. Antonius (Ton) van Helvoort[1], Mr. Viljar J. Femoen[1], MSc Anders C. Mathisen[1], Ms Kaja E. Aune[1], Dr. Emil F. Christiansen[1], Dr. Inger-Emma Nylund[2], Dr. Tina Bergh[1,3], Dr. Ruben Bjørge[1,4]
[1]Department of Physics, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, [3]Department of Chemical Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, [4]Materials and Nanotechnology, SINTEF Industry, Trondheim, Norway , Trondheim, Norway

743 Deep Learning assisted X-ray Microscopy Characterization of Nickel based Metal Matrix composite reinforced with TiC

Dr. Kaushik Yanamandra[1], Dr. Hrishikesh Bale[1], Dr. Rajarshi Banerjee[2], Ria Mitchell[1]
[1]Carl Zeiss Research Microscopy Solutions, Dublin, United States of America, [2]Materials Science and Engineering, University of North Texas, Denton, United States of America

744 Cryo-FIB as a preparation tool for soft X-Ray Tomography: Analysis beyond EM

Dr Chris Parmenter[1], Dr Kenneth Fahy[2]
[1]Nanoscale and Microscale Research Centre, University of Nottingham, Nottingham, UK, [2]SiriusXT, Dublin, Ireland

745 A new protocol for fluorescent quantitative labeling of individual proteins for live cell internalization assays

Dr Juan De Dios Alche[1,3], Dr. Alfonso Clemente[2], Dr. Antonio J. Castro[1]
[1]Department of Stress, Development and Signaling in Plants. Estacion Experimental del Zaidin. CSIC, Granada, Spain, [2]Department of Nutrition, Gastrointestinal Health and Food Safety. Estacion Experimental del Zaidin. CSIC, Granada, Spain, [3]University Institute of Research on Olive Grove and Olive Oils, Jaen, Spain

746 New protein fluorescent labeling methods for carbonylation and S-acylation studies in plants

MSc Andrea Román[1,2], MSc Salvador Priego[1,2], Ph.D. Antonio J. Castro[1], Dr Juan De Dios Alche[1,3]
[1]Plant Reproductive Biology and Advanced Imaging Laboratory (BReMAP), Estación Experimental del Zaidín (CSIC), Granada, Spain, [2]These authors contributed equally to this work, , Spain, [3]University Institute of Research on Olive Grove and Olive Oils (INUO), Jaén, Spain

747 Supersilent AlCoFeNiCux (x = 0.6 – 3.0) high-entropy alloys

Dr. Andreja Jelen[1]
[1]J. Stefan Institute, Ljubljana, Slovenia

748 Development and characterization of a laser-driven cold-field emission source
Alexander Schröder[1], Mukai Masaki[2], Kohno Yuji[2], Sascha Schäfer[1,3]
[1]Department of Physics, University of Regensburg, Regensburg , Deutschland, [2]JEOL Ltd., , Japan, [3]Regenburg Center for Ultrafast Nanoscopy (RUN), Regensburg, Germany
749 Microchannel Plate-based Detector with High Pressure Operation up to 1 Pa for Scanning Electron Microscopy
Mr Masahiro Hayashi[1], Mr. Yuya Washiyama[1], Dr. Matthias Sachsenhauser[2]
[1]Hamamatsu Photonics K.K., Hamamatsu , Japan, [2]Hamamatsu Photonics Deutschland GmbH, Herrsching, Germany
750 Solving the crystallographic phase problem by linearizing dynamical electron diffraction
Prof. Christoph Koch[1], Sam Fairman[1], Grigory Kornilov[1], Dr. Benedikt Haas[1], Dr. Niklas Delby[2]
[1]Humboldt-Universität zu Berlin, Dept. of Physics & Center for the Science of Materials Berlin, Berlin, Germany, [2]Bruker AXS (formerly Nion Co. R&D), Kirkland, USA
751 Structural and spectroscopic studies of Cu-doped NiO thin films
Mr Ahmad Althumali[1,2], Mr Ibrahim Aldawood[1], Mr Umit Dogan[3], Dr Adam Kerrigan[4], Dr Leonardo Lari[1,4], Dr Fahrettin Sarcan[3], Prof Ayse Erol[3], Prof Lidija Šiller[5], Prof Vlado K. Lazarov[1,4]
[1]School of Physics, Engineering and Technology, University of York, York , United Kingdom, [2]Department of Physics, Faculty of Science, Taif University, Taif , Saudi Arabia, [3]Department of Physics, Faculty of Science, Istanbul University, Istanbul, Turkey, [4]The York-JEOL Nanocentre, University of York, York, United Kingdom, [5]School of Engineering, Newcastle University, Newcastle upon Tyne , United Kingdom
752 From DNA Nanotechnology to biomedical insight: Towards single-molecule spatial omics
Prof. Dr. Ralf Jungmann[1]
[1]Max Planck Institute of Biochemistry, Martinsried, Germany, [2]LMU Munich, Munich, Germany
753 Band gap shifts in Ga-doped ZnO using momentum-resolved EELS
Cana Elgvin[1], Dario A. Leon[2], Phuong D. Nguyen[1], Fredrik S. Hage[1], Kristian Berland[2], Øystein Prytz[1]
[1]Department of Physics, University of Oslo, Oslo, Norway, [2]Norwegian University of Life Sciences (NMBU), Ås, Norway
754 Structure and mechanism of Zorya anti-phage defense system
Researcher Haidai Hu[1], Thomas C.D. Hughes[2], Doctor Philipp F. Popp[3], Aritz Roa-Eguiara[1], Freddie J.O. Martin[1], Nicole R. Rutbeek, Ivo Alexander Hendriks[4], Leighton J. Payne[2], Yumeng Yan[1], Victor Klein de Sousa[1], Yong Wang[5], Michael Lund Nielsen[4], Richard M. Berry[7], Marc Erhardt[3], Simon A. Jackson[2], Nicholas M.I. Taylor[1]

760 Gallium liquid bridge evolution on varied substrates

Le Shu[1], Ningyan Cheng[1], Long Ren[2], Binghui Ge[1]
[1]Institutes of Physical Science and Information Technology, Anhui University, Hefei, China, [2]International School of Materials Science and Engineering, Wuhan University of Technology, Wuhan, China

761 Multiplexed 3D imaging of single-cell organization and tissue morphology in the multicellular intestinal organoid

Nicole Repina[1], Enrico Tagliavini[1], Marius Mählen[1], Joel Lüthi[3], Manan Lalit[2], Florian Jug[2], Virginie Uhlmann[3], Prisca Liberali[1]
[1]Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland, [2]Human Technopole, Milan, Italy, [3]BioVision Center, University of Zurich, Zurich, Switzerland

762 Achieving methanol photo-oxidation to hydrogen and formaldehyde over lead-free halide perovskite

Mr Zhiyang Zhong[1,2], Prof Shik Chi Edman Tsang[2], Prof Angus Kirkland[1,3]
[1]Department of Materials, University of Oxford, Oxford, UK, [2]Department of Chemistry, University of Oxford, Oxford, UK, [3]Rosalind Franklin Institute, Harwell Campus, Didcot, UK

763 In-situ TEM ion irradiation studies of layered MAX phase materials

Mrs Eman Al Ruqeishi[1], Max Rigby-Bell[2], Graeme Greaves[3], Alexander Eggeman[1], Sarah Haigh[1]
[1]University of Manchester, Manchester, United Kingdom, [2]UK Atomic Energy Authority, Abingdon, United Kingdom, [3]University of Huddersfield, Huddersfield, United Kingdom

764 Nanoscale tribology of hair fibres over large displacements

Dr James Bowen[1]
[1]The Open University, Milton Keynes, UK

765 Manufacture and calibration of high stiffness AFM cantilevers

Dr James Bowen[1], Dr David Cheneler, Dr James Vicary
[1]The Open University, Milton Keynes, UK
766 Solvent-induced softening of polymethyl methacrylate surfaces
Dr James Bowen[1], Dr Simon Collinson
[1]The Open University, Milton Keynes, UK
767 In-situ oxidation and reduction study of Ni/NiO by open cell environmental TEM
Mrs Arej Eid[1,2], Mr Leonardo Lari[1,3], Mr Adam Kerrigan[3], Mr Ahmed Althumali[1,4], Mrs Lidija Siller[5], Mr Vlado Lazarov[1,3]
[1]School of Physics, Engineering and Technology, University of Yorm, York,, United Kingdom, [2]Physics Department , Faculty of sience, University of Tabuk, Tabuk; Postal Code: 71491; P.O. Box: 741 , Saudi Arabia, [3]The York-JEOL Nanocentre, University of York, York, , United Kingdom, [4]Physics department, Faculty of Science, Taif University, Taif,, Saudi Arabia, [5]School of Engineering, Newcastle University, Newcastle upon Tyne,, United Kingdom
768 Crystalline analysis by W-SEM using a newly developed EBSD detector
Dr. Yohei Kojima[1], Yuta Matsumoto[1], Daniel Goran[2], John Gilbert[2], Naoki Kikuchi[1]
[1]JEOL, Ltd., 3-1-2, Musashino, Akishima, Japan, [2]Bruker Nano GmbH, Am Studio 2D, Germany
769 Atomic-resolution investigation of 2D hematene
Phd Jana Dzibelova[1], Jan Filip[2], Jani Kotakoski[1]
[1]University of Vienna, Vienna, Austria, [2]Czech Advanced Technology and Research Institute, Palacky University, Olomouc, Czech Republic
770 An Improved Method for Growing Primary Neurons on Electron Microscopy Grids Co-Cultured with Astrocytes
Mrs Ishika Kumar[1], Mrs Anju Paudyal[2], Mrs Anna Kádková[3], Mrs Michelle Stewart[2], Mr Jakob Balslev Sørensen[3], Mrs. Julika Radecke[1,3]
[1]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, United Kingdom, [2]Mary Lyon Centre at MRC Harwell, Harwell Campus, Didcot, United Kingdom, [3]Department of Neuroscience, University of Copenhagen, Copenhagen, Denmark
771 Microstructure and thermal stability of ultrafine-grained CuZn5 processed by HPT
Yuting Dai[1,2], M.Sc. Marcel Sos[2], Prof. Christian Kübel[1,2]
[1]Institute of Nanotechnology, Karlsruhe Institute of Technology, Karlsruhe, Germany, [2]Department of Materials and Earth Sciences, Technical University Darmstadt, Darmstadt, Germany
772 Microstructural Influence on Sodium Filament Growth in All Solid-state Batteries
Dr. Ziming Ding[1], Dr. Yushu Tang[1], Till Ortmann[2], Dr. Janis Kevin Eckhardt[2], Dr. Marcus Rohnke[2], Dr. Georgian Melinte[1], Prof. Dr. Christian Heiliger[2], Prof. Dr. Jürgen Janek[2], Prof. Dr. Christian Kübel[1,3]

773 Cryo-EM and ED are driving structural studies at the University of Warsaw
Dr Tomasz Góral[1], Dr Szymon Sutuła[1], Prof Krzysztof Woźniak[1,2,3]
[1]Cryomicroscopy and Electron Diffraction Core Facility,Centre of New Technologies, University of Warsaw, Warsaw, Poland, [2]Biological and Chemical Sciences Research Centre, University of Warsaw, Warsaw, Poland, [3]Department of Chemistry, University of Warsaw, Warsaw, Poland
774 Observation of logic states of HfO2-based ferroelectric FETs using STEM-DPC
Thorgund Nemec[1,2], Dirk Utess[1], Stefan Duenkel[1], Martin Weisheit[1], Halid Mulaosmanovic[1], Sven Beyer[1], Moritz Andreas Meyer[1]

[1]GlobalFoundries Dresden Module One LLC & Co. KG, Dresden, Germany, [2]Institute of Materials Science, Faculty of Mechanical Science and Engineering, Dresden Technical University, Dresden, Germany

775 Novel, low-cost hardware for 'STEM in SEM' imaging

Mr Andrew Sturt[1], Dr Gareth Hughes[1], Dr Ian Griffiths[2], Dr Phani Karamched[1], Dr Neil Young[1]
[1]Department of Materials, University of Oxford, , United Kingdom, [2]JEOL (UK) Ltd, Welwyn Garden City, United Kingdom

776 Structural phase transition induced microstructure changes in V2O3 based hybrid magnetic heterostructures

Prof. Unnar Arnalds[1]
[1]University of Iceland, Reykjavik, Iceland

777 In situ closed-cell microscopy study of Ti3C2Tz MXene

Phd Student Changjie Huang[1], Asst. Prof. Leiqiang Qin[2], Prof. Johanna Rosen[2], Prof. Per O.Å Persson[1], Assoc. Prof. Justinas Palisaitis[1]
[1]Thin Film Physics Division, Department of Physics, Chemistry and Biology (IFM), Linköping University, Linköping, Sweden, [2]Material Design Division, Department of Physics, Chemistry and Biology (IFM), Linköping, Sweden

778 Exploring Cell-Material Interactions at Focal Adhesion Points

Dr Krzysztof Berniak[1], Dr Daniel P. Ura[1], Prof. Adam Piórkowski[2], Prof. Urszula Stachewicz[1]
[1]Faculty of Metals Engineering and Industrial Computer Science, AGH University of Krakow, Kraków, Polska, [2]Department of Biocybernetics and Biomedical Engineering, AGH University of Krakow, Kraków, Polska

779 The effect of fixation-induced cell blebbing: how to minimize a loss of proteins from cells?

Prof. Pavel Hozak[1]
[1]Institute of Molecular Gentics ASCR, Prague, Czech Republic

780 Platform for the in-situ measurement of magnetic transport properties in the transmission electron microscope

Sebastian Schneider[1,2], Steven Waddy[1], Takanori Sato[1], Vijay Bhatia[1], Yevheniy Pivak[3], David J. Reilly[1], Bernd Rellinghaus[2], Julie M. Cairney[1], Magnus Garbrecht[1]
[1]The University Of Sydney, Sydney Microscopy And Microanalysis, Sydney, Australia, [2]Dresden Center for Nanoanalysis (DCN), TU Dresden, Dresden, Germany, [3]DENSsolutions, , Netherlands

781 The development of multimodal imaging with functional silica nanoparticle

Dr. Tomohiro Haruta[1], Prof. Michihiro Nakamura[2]
[1]JEOL Ltd., Akishima, Japan, [2]Graduate school of medicine,Yamaguchi university, Ube, Japan

782 Hybrid electrospun scaffolds for enhanced collagen formation in regeneration processes: electron and confocal microscopy analysis

Dr Joanna Karbowniczek[1], Dr Krzysztof Berniak[1], Prof. Urszula Stachewicz[1]
[1]Faculty of Metals Engineering and Industrial Computer Science, AGH University of Krakow, Krakow, Poland

783 Self-assembly of amphiphilic dendrimers investigated by standard, cryo and liquid TEM

Dr Tom ROUSSEL[1], Pr Ling PENG[1], Pr Suzanne GIORGIO[1]
[1]CINAM - CNRS- Aix Marseille University, Marseille, France

784 Microglial contactology–mapping the connection network of microglia from the micrometer to the nanometer range

Phd Anett Dóra Máté-Schwarcz[2], Dr. Csaba Cserép[1], Dr. Eszter Szabadits[1], Dr. Ádám Dénes[1]
[1]Neuroimmunology Laboratory, HUN-REN Institute of Experimental Medicine, Budapest, Hungary, [2]János Szentágothai, Semmelweis University Doctoral School of Neuroscience, Budapest, Hungary

785 Insights on the disordered nature in amorphous-based anode materials from Electron Pair Distribution Function
Dr. Anuj Pokle[1], Marte Orderud Skare[2], Shihui Feng[3], Dr Cheuk Wai Tai[3], Dr Asbjørn Ulvestad[2], Prof Xiaodong Zou[3], Prof Øystein Prytz[1]
[1]Department of Physics and Center for Materials Science and Nanotechnology, University of Oslo, Oslo, Norway, [2]Department of Battery Technology, Institute for Energy Technology, Kjeller, Norway, [3]Department of Materials and Environmental Chemistry, Arrhenius Laboratory, Stockholm University, Stockholm, Sweden
786 The nature of diffuse scattering in fcc metal alloys –
investigation by 3D-ED and 4D-STEM
Hannah Cole[1], Mr James Miller[1], Mr James Hogg[1], Mr Petr Vacek[1], Mr Owain Houghton[1], Prof Howard Stone[1], Prof Paul Midgley[1]
[1]Department of Materials Science & Metallurgy, University of Cambridge, Cambridge,, United Kingdom
787 Microstructural assessment of mechanically alloyed low activation 9-Cr oxide-dispersion strengthened steels
Dr. Michael Thomas Duerrschnabel[1], Dr. Carsten Bonnekoh[1], Ute Jäntsch[1], Siegfried Baumgärtner[1], Henning Zoz[2], Dr. Michael Rieth[1]
[1]Karlsruhe Institute of Technology (KIT), Institute of Applied Materials, Hermann von Helmholtz Platz 1, Eggenstein-Leopoldshafen, Germany, [2]Zoz Group, Maltozstraße, Wenden, Germany
788 Cholesteatoma removal efficiency evaluated by Variable Pressure Scanning Electron Microscopy
Prof Michela Relucenti[1], Prof Edoardo Covelli[2], Prof Orlando Donfrancesco[1], Prof Giuseppe Familiari[1], Prof Maurizio Barbara[2]
[1]Department of Anatomical, Histological, Forensic and Orthopedic Sciences, Section of Human Anatomy, Sapienza University of Rome, Rome, Italy, Rome, Italy, [2]Department of Neuroscience, Mental Health and Sensory Organs (NEMOS), Sapienza University of Rome, Rome, Italy, Rome, Italy
789 3D Electron Diffraction Study on the Local Structure of a doped Metal-organic Framework TCNQ@ZIF-4
Dr. Jianbo Song[1], Dr. Zhehao Huang[1]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden
790 Structural study of perovskite-structure transition metal oxide thin film using Cs-corrected STEM: case of $LaVO_3/DyScO_3$
Chih-ying Hsu[1,2], Clementine Thibault[1], Pau Torruella[2], Jean-Marc Triscone[1], Stefano Gariglio[1], Duncan T.L. Alexander[2]
[1]Department of Quantum Matter Physics, University of Geneva, Geneva, Switzerland, [2]Electron Spectrometry and Microscopy Laboratory (LSME), Institute of Phyiscs (IPHYS), École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland
792 Restructuring of silver catalysts after oxidation reactions
– looking beneath the surface
Dr Tina Bergh[1], Youri van Valen[1], Jia Yang[1], Ole H. Bjørkedal[2], Ann Kristin Lagmannsveen[3], Hilde J. Venvik[1]
[1]Department of Chemical Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, [2]Dynea AS, Lillestrøm, Norway, [3]K.A. Rasmussen, Hamar, Norway
793 Deep learning powered light optical microscopy for steel reseach
Dr. Sarka Mikmekova[1], Dr. Martin Zouhar[1], Jan Čermák[1], Ondřej Ambrož[1], Patrik Jozefovič[1], Dr. Jiří Materna[2]
[1]Institute of Scientific Instruments of the CAS, Brno, Czech Republic, [2]Machine learning college, Brno, Czech Republic

794 High quality graphene TEM supports for high-resolution transmission electron microscopy
Jenthe Verstraelen[1], Dr. Adrian Pedrazo Tardajos[1], Dr. Nathalie Claes[1], Dr. Tine Derez[1], Prof. Dr. Sara Bals[1]
[1]EMAT, university of Antwerp, Antwerp, Belgium
795 Application of secondary electron hyperspectral imaging to the analysis of pharmaceutical materials
Stuart Micklethwaite[1], Rastra Basnet[1], Joseph Ma[1], Daniel Hopper[1], James Nohl[2], Nicholas Farr[2], Cornelia Rodenburg[2], Dr Nicole Hondow[1]
[1]University of Leeds, Leeds, UK, [2]University of Sheffield, Sheffield, UK
796 Immunoexpression of estrogen receptor α in the ovary of mice after chronic exposure to arsenic(III)-oxide

Ass.prof. Marija Marin[1], Anita Birinji[1], Full prof. Anita Radovanović[2], Ass.prof. Maja Čakić-Milošević[1], Full prof. Dušan Lalošević[3]
[1]University of Belgrade, Faculty of Biology, Belgrade, Serbia, [2]University of Belgrade, Faculty of Veterinary Medicine, Belgrade, Serbia, [3]University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia
797 Structural recognition and stabilization of tyrosine hydroxylase by the J-domain protein DNAJC12
Mrs. Mary Dayne S. Tai[1], Mrs. Jimena Munatner[2], Mrs. Lissette Ochoa[2], Mrs. Marte I. Flydal[1,3], Mrs. Lorea Velasco[4], Mr. César Santiago[2], Mr. Kunwar Jung-KC[1,5], Mr. Svein I. Støve[1,5], Mr. Fernando Moro[4], Mr. Juha P. Kallio[1], Mr. Arturo Muga[4], Mr. José María Valpuesta[2], Mr. Jorge Cuéllar[2], Mrs. Aurora Martínez[1,5]
[1]Department of Biomedicine and K.G. Jebsen Center for Translational Research in Parkinson's Disease, Bergen, Norway, [2]Centro Nacional de Biotecnología (CNB-CSIC), Madrid, Spain, [3]Department of Medical Genetics, Haukeland University Hospital, Bergen, Norway, [4]Instituto Biofisika (UPV/EHU, CSIC), Universidad del País Vasco, (UPV/EHU), and Departamento de Bioquímica y Biología Molecular, Facultad de Ciencia y Tecnología, Universidad del País Vasco, (UPV/EHU), Leioa, Spain, [5]Neuro-SysMed, Department of Neurology, Haukeland University Hospital, Bergen, Norway
798 STRUCTURAL CHARACTERIZATION OF FZD7, THE IMPORTANCE OF WATER NETWORK AND CHOLESTEROL FOR CLASS F GPCRS
PhD Julien Bous[1], Kinsolving Julia[1], PhD Lukas Grätz[1], PhD Magdalena Scharf[1], PhD Jan Voss[1], Berkay Selcuk[2], PhD Ogün Adebali[3], PhD Gunnar Schulte[1]
[1]Section of Receptor Biology & Signaling, Department of Physiology & Pharmacology, Karolinska Institutet, Stockholm, Sweden, [2]Department of Microbiology, The Ohio State University, Colombus, USA, [3]Faculty of Engineering and Natural Sciences, Sabanci University, Istanbul, Turkiye
799 Towards Quantitative analysis of electrostatic potential of monolayer WSe2 using electron ptychography
Yiran Lu[1], Alexis Wartelle[1], Djodje Dosenovic[2], Matthew Bryan[3], Hanako Okuno[2], Julio-Cesar da Silva[1], Jean-Luc Rouvière[4], Martien I. den Hertog[1]
[1]Univ. Grenoble-Alpes, CNRS, Grenoble INP, Institut Néel, Grenoble, France, [2]Univ. Grenoble-Alpes, CEA, Grenoble INP, IRIG, PHELIQS, Grenoble, France, [3]CEA, LETI, Grenoble, France, [4]Univ. Grenoble-Alpes, CEA-IRIG, MEM, Grenoble, France
800 Functional and Structural Insights into the Modulation of the Chaperonin CCT by Small Molecules
Mr. Sergio Pipaón[1], Mr. Svein I. Støve[2], Mrs. Elena Pascual[3], Mrs. Carmen Majano[1], Mrs. Isabel García-Álvarez[3], Mr. Alberto Grande[1], Mrs. Mercedes Núñez[4], Mrs. Aurora Martínez[2], Mr. Jorge Cuéllar[1], Mr. José María Valpuesta[1]
[1]National Center for Biotechnology (CNB-CSIC), Cantoblanco, Spain, [2]Department of Biomedicine, University of Bergen, Bergen, Norway, [3]Faculty of Experimental Sciences, Francisco de Vitoria

University (UFV), Pozuelo de Alarcón, Spain, [4]Severo Ochoa Molecular Biology Center (CBMSO-CSIC), Cantoblanco, Spain

801 Using super-resolution imaging to understand protein organization within Z-discs of striated muscle.

Prof Michelle Peckham[1], Dr Alistair Curd[1], Dr Ruth Hughes[1], Dr Heather Martin[1], Dr Anna Tang[1], Dr Francine Parker[1], Dr Christian Tiede[1], Dr Darren Tomlinson[1]

[1]Faculty of Biological Sciences, University of Leeds, Leeds, UK

802 Determination of Ti3C2Tx Mxene few layers stacks architecture using valence EELS and diffraction

Dr Jerome Pacaud[1], Dr Haw-Wen Hsiao[2], Dr Renliang Yuan[2], Dr Stephane Celerier[4], Pr Jian-Min Zuo[2], Pr Vincent Mauchamp[1], Dr Thomas Bilyk[3]

[1]Institut Pprime – UPR 3346 – CNRS, Université de Poitiers, Poitiers, France, [2]Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, Urbana, USA, [3]Université Paris-Saclay, CEA, Service de recherche en Corrosion et Comportement des Matériaux, SRMP, Gif-sur-Yvette, France, [4]IC2MP – UMR 7285 – CNRS, Université de Poitiers, Poitiers, France

803 Analysis of fire gilding on medieval jewellery using focused ion beam

Jan Manak[1], Jan Duchon[1], Estelle Ottenwelter[2]

[1]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic, [2]Institute of Archaeology of the Czech Academy of Sciences, Prague, Czech Republic

804 Denoising 4D STEM datasets with PCA

Leonid Potapov[1], Mingjian Wu[2]

[1]temDM, Dresden, Germany, [2]IMN&CENEM, Friedrich-Alexander Universität, Erlangen-Nürnberg, Germany

805 Nanotubes of (SmxY1-x)S-TaS2 based on Quaternary Misfit Layered Compounds (MLCs)

Mr Mohammad Furqan[1], Dr Simon Hettler[1,2], Dr MB Sreedhara[3], Dr Reshef Tenne[4], Dr Raul Arenal[1,2,5]

[1]Laboratorio de Microscopias Avanzadas (LMA), Universidad de Zaragoza, Zaragoza, Spain, , , [2]Instituto de Nanociencia y Materiales de Aragón (INMA), Universidad de Zaragoza, Zaragoza, Spain, , , [3]Solid State and Structural Chemistry Unit, Indian Institute of Science, Bengaluru, India,, , , [4]Department of Molecular Chemistry and Materials Science, Weizmann Institute of Science, Rehovot, Israel, , , [5]ARAID Foundation, Zaragoza, Spain, ,

806 Multicore@shell nanoparticles synthesized from a multicomponent target by gas aggregation cluster source

Marie Elis[1], Dr. Amir Mohammad Ahadi[2], Tim Tjards[3], Dr. Alexander Vahl[3,4,5], Dr. Salih Veziroglu[3,4], Dr. Thomas Strunskus[3,4], Prof. Dr. Franz Faupel[3,4], Dr. Ulrich Schürmann[1,4], Prof. Dr. Lorenz Kienle[1,4]

[1]Chair for Synthesis and Real Structure, Department for Materials Science, Faculty of Engineering, Kiel University, Kiel, Germany, [2]Department of Physics, Faculty of Science, Shahid Chamran University of Ahvaz, Ahvaz, Iran, [3]Chair for Multicomponent Materials, Department for Materials Science, Faculty of Engineering, Kiel University, Kiel, Germany, [4]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, Kiel, Germany, [5]Leibniz Institute for Plasma Science and Technology, Greifswald, Germany

807 Minimising the distortive effects of diffraction on magnetic STEM-DPC imaging of monocrystalline thin films

Sivert Dagenborg[1], Andrea D'Alessio[2], Nikolas Vitaliti[2], Alessandro Palliotto[2], Eric Brand[2], Associate Professor Ingrid Hallsteinsen[3], Professor Nini Pryds[2], Assistant Professor Daesung Park[2], Associate Professor Felix Trier[2], Associate Professor Magnus Nord[1]

[1]Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway, [2]Department of Energy Conversion and Storage, Technical University of Denmark, Kongens Lyngby, Denmark, [3]Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway

808 Operando Environmental TEM observations of SOEC Ni-YSZ fuel electrode dynamics
Mr. Magnus Björnsson[1], Mr. Søren Simonsen[1], Mr. Ming Chen[1]
[1]Department of Energy Conversion and Storage, The Danish Technical University, Kgs. Lyngby, Denmark
809 Inflammatory mechanism in Diabetes – Ultrastructural investigations of endocrine pancreas using correlative electron microscopy (STEM)
Dr. Dagmar Kolb[1,2], Bsc. Sumayya Böhm[1], Kerstin Hingerl[1], Prof. Thomas Pieber[3,4], Msc. Barbara Ehall[3,4], Bsc. Dominique Pernitsch[1], DI Lea Bogensperger[5]
[1]Core Facility Ultrastructure Analysis - Center for Medical Research, Graz, AUSTRIA, [2]Gottfried Schatz Research Center, Division of Cell Biology, Histology and Embryology, Graz, AUSTRIA , [3]Division of Endocrinology and Diabetology, Medical University of Graz, , , [4]The Center for Biomarker Research in Medicine GmbH, , , [5]Institute of Computer Graphics and Vision, Graz University of Technology, ,
810 Structure and Composition of High-Entropy-Alloy Nanoparticle synthesized by Pulsed Laser Ablation in Liquid
Felix Pohl[1], Robert Struckert[2], Dr. Ulrich Schürmann[1], Dr. Christoph Rehbock[2], Prof. Stephan Barcikowski[2], Prof. Lorenz Kienle[1]
[1]Institute for Material Science, Faculty of Engineering, Kiel University, Kiel, Germany, [2]Technical Chemistry I and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Essen, Germany
811 Towards customized in situ TEM Chips for “device-like” geometries
Marthe Linnerud[1], Ingrid Hallsteinsen[2], Magnus Nord[1]
[1]Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway, [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway
812 Structure of refractory high entropy alloy and high entropy nitride thin films
Doctor Dimitri Litvinov[1], Doctor Michael Stüber, Professor Sven Ulrich[1], Professor Jarir Aktaa[1]
[1]Institute for Applied Materials, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany
813 Fast nanoparticle passage over cell membrane identified using 3D STED cross-sectional imaging
Dr. Boštjan Kokot[1], Hana Kokot[1], Janez Štrancar[1]
[1]J. Stefan Institute, Ljubljana, Slovenia
814 An examination of exit-wave reconstruction algorithms for low dose imaging at atomic-scale resolution
Jacob Svane-Petersen[1], Andreas Nymand[1], Joerg R. Jinschek[1,2], Stig Helveg[1], Joakim Kryger-Baggesen[1], Sophie Kargo Kaptain[1]
[1]Center for Visualizing Catalytic Processes (VISION), Technical University of Denmark, Kgs. Lyngby, Denmark, [2]Nanolab, Technical University of Denmark, Kgs. Lyngby, Denmark
815 Examination of the Pathophysiology of Peripheral Olfactory Dysfunction and Alpha Melanocyte Stimulating Hormone Therapy
Oğuzhan Ekici[1], Prof. Dr. Gamze Tanriverdi[2], RA Hakan Sahin[2], Prof. Dr. Hafize Uzun[3], RA Mediha Eser[4], Prof. Dr. Gonul Simsek[1]
[1]Department of Physiology, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, İstanbul, Turkey, [2]Department of Histology and Embryology, İstanbul University-Cerrahpasa Faculty of Medicine, İstanbul, Turkey, [3]Department of Medical Biochemistry, İstanbul Atlas University, Faculty of Medicine, İstanbul, Turkey, [4]Department of Histology and Embryology, Altınbas University, Faculty of Medicine, İstanbul, Turkey
816 Simultaneous Indexing of Spot and Kikuchi Patterns in Scanning Electron Microscopy (SEM)
PhD Student Yuxuan Zhang[1], Senior Researcher Alice Bastos da Silva Fanta[1], Professor Jakob Schiøtz[2]

[1]DTU Nanolab, Technical University of Denmark, Lyngby, Denmark, [2]DTU Physics, Technical University of Denmark, Lyngby, Denmark

817 Physical determinants of YAP mechanotransduction in multicellular assemblies

Valeriia Grudtsyna[1]
[1]Niels Bohr Institute, Copenhagen, Denmark

818 Dual-color CLEM imaging for genetically encodable enzymatic fluorescence signal amplification method using APEX (FLEX)

Dr. Min Kyo Jung[1], Dr. Nirmali Sharma[2,3], Dr. Pratyush Kumar Mishra[2], Prof. Hyun-Woo Rhee[2,4], Dr. Ji Young Mun[1]
[1]Neural Circuits Research Group, Korea Brain Research Institute, Seoul, Korea, [2]Department of Chemistry, Seoul National University, Seoul , Korea, [3]Department of Chemistry, Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, [4]School of Biological Sciences, Seoul National University, Seoul, Korea

819 Multimodal mechano-microscopy reveals mechanical phenotypes of breast cancer spheroids in three dimensions

Alireza Mowla[1,2], Dr Liisa Hirvonen[3], Matt Hepburn[1,2,4], Jiayue Li[1,2], Danielle Vahala[5], Sebastian Amos[5], Rowan Sanderson[1,2], Philip Wijesinghe[6], Samuel Maher[5], Yu Suk Choi[5], Brendan Kennedy[1,2,4]

820 Transmission electron microscopy studies of ferroelectric ZrO2 thin films

Phd Student Marian Cosmin Istrate[1], Dr Corneliu Ghica[1], Dr Jose Pedro Basto Silva[2]
[1]National Institute of Materials Physics, 105 Bis Atomistilor, 077125, Magurele, Romania, [2]Physics Center of Minho and Porto Universities (CF-UM-UP), University of Minho, Campus de Gualtar, 4710-057, Braga, Portugal

821 Characterization of the structure and chemistry of solid electrolyte

Dr Kyung Song[1], Dr Abin Kim[2], Professor Byungwoo Kang[2]
[1]Korea Institute of Materials Science , Changwon, Republic of Korea, [2]Pohang University of Science and Technology , Pohang, Republic of Korea

822 Liquid Phase 3D Electron Diffraction Combination Provides New Possibilities for Polymorphism Studies

Joakim Lajer[2], Edward T. Broadhurst[1], Murat N. Yesibolati[2], Emil C. S. Jensen[3], Xiaodong Zou[1], Kristian S. Mølhave[2], Hongyi Xu[1], Huiqiu Wang[1]
[1]Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden, [2]National Centre for Nano Fabrication and Characterization, Technical University of Denmark, Lyngby, Denmark, [3]Insight Chips Aps, Lyngby, Denmark

823 Charge density mapping of supported nanoparticle electrocatalysts by 4D STEM

Lazar Bijelic[1,2], Ana Rebeka Kamšek[1,3], Francisco Ruiz Zepeda[1], Goran Dražić[1], Nejc Hodnik[1,2]
[1]National Institute of Chemistry, Ljubljana, Slovenia, [2]University of Nova Gorica, Nova Gorica, Slovenia, [3]Faculty of Chemistry and Chemical Engineering, University of Ljubljana, Ljubljana, Slovenia

824 Correlative study of hematite-based photoanodes for solar water splitting by transmission electron and X-ray microscopies

Léon Schmidt[1], Bilal Meddas[2], Walid Baaziz[1], Dana Stanescu[2], Stefan Stanescu[3], Ovidiu Ersen[1]

[1]IPCMS CNRS / Université de Strasbourg, Strasbourg, France, [2]SPEC CEA Saclay / CNRS, Gif sur Yvette, France, [3]Synchrotron SOLEIL, Saint-Aubin, France

825 Entanglement in Bragg Scattering

Ao. Univ. Prof. Peter Schattschneider[1], Assoc.-prof. Stefan Löffler[1]
[1]TU Wien, Wien, Austria

826 Three-dimensional, correlative electron microscopy and immuno-labelling revealed new principles of the Golgi complex functioning

Prof. M.D.; PhD.; DcS. Alexander Mironov[1], MD, PhD, DcS Galina Beznoussenko[1]
[1]IFOM ETS—The AIRC Institute of Molecular Oncology, Milan, Italy

827 Guided growth of 1D van der Waals Nanowires for Enhanced Optoelectronic Functionalities

Maayan Persky[1], Shahar Bialer[1], Noya Ruth Itzhak[1], Anna Eden Kossoy[2], Lotar Houben[2], Ernesto Joselevich[1]
[1]Department of Molecular Chemistry and Materials, Weizmann Institute of Science Science,, Rehovot, Israel, [2]Chemical Research Support, Weizmann Institute of Science, Rehovot, Israel

828 Detailed TEM Studies of 1D Nanostructures based on Layered Cobalt Oxide

Dr Raul Arenal[1,2,3], Dr Simon Hettler[1,2], Mrs Kankona Roy[4], Dr. Leela Panchakarla[4]
[1]Instituto de Nanociencia y Materiales de Aragón, CSIC-Universidad de Zaragoza, Zaragoza, Spain., Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas, Universidad de Zaragoza. Zaragoza, Spain, Zaragoza, Spain, [3]Araid Foundation, Zaragoza, Spain, Zaragoza, Spain, [4]Department of Chemistry, Indian Institute of Technology Bombay, , Powai, Mumbai, 400076, India

829 Microscopic characterization of graphene derivates in life science

Mgr. Jana Straska[1,2]
[1]Czech Advanced Technology and Research Institute - Regional Centre of Advanced Technologies and Materials, Olomouc, Czech Republic, [2]VSB Tech Univ Ostrava, IT4Innovations, Ostrava, Czech Republic

830 Microscopic characterization of graphene derivates in life science

Mgr., Phd Zuzana Chaloupkova[1,2], Mgr. Jana Straska[1,2]
[1]Czech Advanced Technology and Research Institute - Regional Centre of Advanced Technologies and Materials, Olomouc, Czech Republic, [2]VSB Tech Univ Ostrava, IT4Innovations, Ostrava, Czech Republic

831 3D calibration for SEM and optical microscopy - First results with next generation 3D standards

Dr.-Ing. Matthias Hemmleb[1], Celina Hellmich[2], Lena Heinrich[2], Sebastian Buetefisch[2]
[1]point electronic GmbH, Halle (Saale), Germany, [2]PTB Physikalisch-Technische Bundesanstalt, Braunschweig, Germany

832 Exit of different cargoes from the Golgi and their post-Golgi trafficking

Dr. Galina Beznoussenko[1], PhD, MD, Prof. Alexander Mironov[1]
[1]IFOM ETS, The AIRC Institute of Molecular Oncology, Via Adamello 16, 20139, Milan, Italy, Milan, Italy

833 FIB-induced nanorod formation in 2D layered crystals

Dr. Julia Deuschle[1], Dr. Tobias Heil[1], Dr. Hongguang Wang Hongguang Wang[1], Prof. Dr. Peter van Aken[1]
[1]Max Planck Institute for Solid State Research, Stuttgart, Germany

834 Sub-nanometer mapping of strain-induced band structure variations in different semiconductor device configurations

Marc Botifoll[1], Dr. Sara Martí-Sánchez[1], Dr. Eitan Oksenberg[2], MSc. Christian Koch[1], MSc. Carla Borja[1], Dr. Maria Chiara Spadaro[1], Dr. Valerio Di Giulio[3], Prof. Quentin Ramasse[4,5], Prof. F. Javier García de Abajo[3,6], Prof. Ernesto Joselevich2[2], Prof. Jordi Arbiol[1,6]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Bellaterra, 08193 Barcelona, Spain, [2]Department of Molecular Chemistry and Materials Science, Weizmann Institute of Science, Rehovot 76100, Israel, [3]ICFO-Institut de Ciencies Fotoniques, The Barcelona Institute of

Science and Technology, 08860 Castelldefels, Barcelona, Spain, [4]SuperSTEM Laboratory, STFC Daresbury Campus, Daresbury WA4 4AD, United Kingdom, [5]School of Chemical and Process Engineering & School of Physics and Astronomy, University of Leeds, Leeds LS2 9JT, United Kingdom, [6]ICREA, Passeig Lluís Companys 23, 08010 Barcelona, Spain

835 Investigating Bone Microstructure with ATUM-SEM: Implications for Pathological Conditions
Ph.d Valeria Vistoso[1], Dr. Tom Fertè[1], Dr. Federica Buccino[2], Professor Laura Maria Vergani[2], Professor Ovidiu Ersen[1], Professor Adele Carradò[1]
[1]Institut de physique et chimie des Matériaux de Strasbourg, University of Strasbourg, Strasbourg, France, [2]Department of Mechanical Engineering, Politecnico di Milano, Milan, Italy

836 Automated Detection of Material Defects for High-throughput Electron Micrographs Analysis
Andrei Tudor Durnescu[1], Sotero Pedro Romero Morón[1], Christina Nicole König[1], Joerg R. Jinschek[1]
[1]Danish Technical University, Lyngby-Taarbaek, Denmark

837 Control of inter-particle distance between nanoparticles using DNA origami
Jannik Guckel[1,2], Dr Daesung Park[1,2], Dr Markus Etzkorn[2,3], Zhe Liu[2,3], Zunhao Wang[1,2], Dr. Birka Lalkens[2,4]
[1]Physikalisch-Technische Bundesanstalt, Braunschweig, Germany, [2]Laboratory for Emerging Nanometrology (LENA), Braunschweig, Germany, [3]Institute of Applied Physics, Technische Universität Braunschweig, Braunschweig, Germany, [4]Institute of Semiconductor Technology, Technische Universität Braunschweig, Braunschweig, Germany

839 Bag1 has a key role in the Hsp70-assisted, proteasome-mediated degradation pathway
Dr Moisés Maestro-López[1], Dr Tat Cheung[2,3], Ms Jimena Muntaner[1], Prof Margarita Menéndez[4], Ms Melissa Alonso[1], Dr Andreas Schweitzer[2,3], Prof José María Valpuesta[1], Phd Jorge Cuéllar[1], Dr Eri Sakata[2,3]
[1]National Centre for Biotechnology (CNB-CSIC), Madrid, Spain, [2]Institute for Auditory Neuroscience, University Medical Center Göttingen, Göttingen, Germany, [3]3Multiscale Bioimaging: from Molecular Machines to Networks of Excitable Cells (MBExC), University of Göttingen, Göttingen, Germany, [4]Instituto de Química-Física Rocasolano (IQFR-CSIC), Madrid, Spain

840 Analysis of epigenetic modifications with the LiveMIEL (Live-cell Microscopic Imaging of Epigenetic Landscapes) approach
Alexandra Shuvaeva[2,3], Elizaveta Khvedelidze[4], Afanasii Stepanov[1,2], Dr. Lidia Putlyaeva[1,2]
[1]Center for Molecular and Cellular Biology, Skolkovo Institute of Science and Technology, Moscow, Russia, [2]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russia, [3]Moscow Institute of Physics and Technology, Dolgoprudny, Russia, [4]D. Mendeleev University of Chemical Technology of Russia, Moscow, Russia

841 The EXCITE² Network: a European infrastructure providing transnational access to leading-edge imaging facilities
Alireza Chogani[1], Oliver Plümper[1], Geertje ter Maat[1], the EXCITE team
[1]Department of Earth Sciences, Utrecht University, Utrecht, The Netherlands

842 Structural Probing of Charging Mechanism in LiNiO2 at High Voltage using Microscopy and Spectroscopy
Dr Jun Chen[1], Dr Mikkel Juelsholt[2], Dr Robert House[1], Prof Peter Bruce[1]
[1]Department of Materials, University of Oxford, Oxford, United Kingdom, [2]Department of Chemical Engineering. Columbia University, New York, United States

843 Advanced acquisition strategies for lab-based diffraction contrast tomography
Florian Bachmann[1], Jun Sun[1], Jette Oddershede[1], Erik Lauridsen[1]
[1]Xnovo Technology ApS, Køge, Denmark

844 Thallium and arsenic incorporation in roméite group minerals
Priv.-Doz. Dr. Tamara Đorđević[1,2], Priv.-Doz. Dr. Michael Stöger-Pollach[1], Dr. Sabine Schwarz[1]

[1]E057-02 USTEM, Vienna University of Technology, Vienna, Austria, [2]Department of Mineralogy and Crystallography, University of Vienna, Vienna, Austria

845 Impact of improved tracking method on structure determination of perovskites from 3D ED data

Dr. Magdalena Cichocka[1]

[1]Technische Universität Darmstadt, Darmstadt, Germany

846 Effects of melatonin and alpha-lipoic acid on collagen and VEGF expression in palatal wound healing

Onur Kutlu[1], Gülten Kavak[1], Aslı Erdoğan Öner[2], Selen Akyol Bahçeci[2]

[1]Department of Oral and Maxillofacial Surgery, İzmir Katip Çelebi University , İzmir, Türkiye, [2]Department of Histology and Embryology, İzmir Katip Çelebi University, İzmir, Türkiye

847 TEMsuite – A Matlab-based software platform for TEM data analysis

Simon Hettler[1,2]

[1]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain, Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza. Zaragoza, Spain, Zaragoza, Spain

848 NiTi shape memory alloy microstructure after high stress at elevated temperatures containing modulated M2 martensite

Jan Duchoň[1], Yuchen Chen[1], Miloslav Klinger[1], Petr Šittner[1]

[1]FZU - Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic

849 Influence of the deposition parameters on properties of gold plasmonic antennas

Michael Foltýn[1], Marek Patočka[1], Rostislav Řepa[1], Tomáš Šikola[1], Michal Horák[1]

[1]Brno University of Technology, Brno, Czech Republic

850 3D TEM and SEM-array tomography of Hailey-Hailey Disease human skin biopsies

Ph.D. Massimo Micaroni[1], P.D. Jens Berndtsson[1], P.D. Rafael Camacho[1], Ph.D. Erin Cocks[1], M.D. Giulio Gualdi[2], Ph.D. Apollonia Tullo[3], Ph.D. Flaviana Marzano[3], M.D. Camilla Marinelli[4], Ph.D. Anna Campanati[5], M.D. Gaetana Lanzi[6], M.D., Ph.D. Manuela Iezzi[7], M.D. Vincenzo Maione[8], M.D., Ph.D. Paolo Amerio[2], Ph.D. Julia Fernandez-Rodriguez[1]

[1]Centre for Cellular Imaging Core Facility, Sahlgrenska Academy, University of Gothenburg, Göteborg, Sweden, [2]Department of Medicine and Aging Science, Dermatology Unit, University “G. d'Annunzio”, Chieti-Pescara, Italy, [3]Institute of Biomembranes, Bioenergetic and Molecular Biotechnology – IBIOM, Bari, Italy, [4]UOSD Pathological Anatomy, ASL 2 Abruzzo, “G. Bernabeo” Hospital, Ortona (CH), Italy, [5]Department of Clinical and Molecular Sciences, Dermatology Clinic, Polytechnic Marche University, Ancona, Italy, [6]Medical Genetics Laboratory, Diagnostic Department, ASST-Spedali Civili of Brescia, Brescia, Italy, [7]Department of Neuroscience, Imaging and Clinical Sciences, Pathology Section, University “G. d'Annunzio” Chieti-Pescara, Chieti-Pescara, Italy, [8]Dermatology, ASST-Spedali Civili of Brescia, Brescia, Italy

851 Precise light and fluorescent microscopy guided sequential cryo FIB lift-out

Dominik Pinkas[1], Samuel Záchej[2], Martina Zanova[2], Prof. Pavel Hozak[3], Vlada Filimonenko[1,3]

[1]Electron Microscopy Core Facility, Institute of Molecular Genetics ASCR, Prague, Czech republic, [2]TESCAN GROUP, Brno, Czech republic, [3]Department of Biology of the Cell Nucleus, Institute of Molecular Genetics ASCR, Prague, Czech republic

852 Nanoscale structural and spectroscopic characterization of hard carbons for Na-ion batteries

Tatiana Kormilina[1], Harald Fitzek[1], Daniel Knez[2], Ilie Hanzu[3], Gerald Kothleitner[1,2], Georg Haberfehlner[2]

[1]Graz Centre for Electron Microscopy, Graz, Austria, [2]Institute of Electron Microscopy and Nanoanalysis, Graz University of Technology, Graz, Austria, [3]Institute for Chemistry and Technology of Materials, Graz University of Technology , Graz, Austria

853 All-Micro: a Network for Sustainable Innovation in Slovenia- Italy Area

Dr. Behnaz Abbasgholi-NA[1], Dr. Simone Dal Zilio[1], Dr. Gabriele Baj[2], Dr. Rita De Zorzi[2], Dr. Gianluca Turco[2], Dr. Claudia Baracchini[3], Dr. Mattia Fanetti[4], Dr. Bojana Cipot[5], Dr. Martina Knavs[6]
[1]Istituto Officina dei Materiali CNR-IOM, Area Science Park-Basovizza, Science Park, Trieste I-34149, Italy, , , [2]Centro Interdipartimentale Microscopia Avanzata CIMA, Università di Trieste, Trieste I 34127, Italy, , , [3]Friuli Innovazione Società consortile a responsabilità limitata Via Jacopo Linussio, 51 - 33100 Udine, Italy, , , [4]University of Nova Gorica, Vipavska 13, Rožna Dolina, SI-5000 Nova Gorica, Slovenia, , , [5]Primorska Technology Park, Mednarodni prehod 6, Vrtojba, 5290 Šempeter pri Gorici, Slovenia, , , [6]Nanocenter, Center odličnosti nanoznanosti in nanotehnologije Jamova 39, SI-1000 Ljubljana, Slovenia, ,

854 Investigating nitrogen doped nanocarbon materials as potential carbon dioxide adsorbers

Ivan Musil[1,2], Venkataprasanna Kannan Sampathkumar[1,2], Jonas Haas[1,2], Kevin Strobel[1,2], Jannik Meyer[1,2]
[1]Institute for Applied Physics, University of Tübingen, Tübingen, Germany, [2]NMI Natural and Medical Sciences Institute at the University of Tübingen, Reutlingen, Germany

855 Achieving High-Resolution Electron Nano-crystallography using HVEM and PED

Master Sang-gil Lee[1], Doctor Seung Jo Yoo[1], Doctor Jin-Gyu Kim[1], Doctor Hyung Joong Yun[1]
[1]Korea Basic Science Institute, Daejeon, South Korea

856 The mixed ionic-electronic conductors studied by advanced transmission electron microscopy

Dr Ke Ran[1,2,3], Dr Fanlin Zeng[4], Dr Liudmila Fischer[4], Dr Stefan Baumann[4], Prof Wilhelm Meulenberg[4,5], Dr Kerstin Neuhaus[6], Prof Joachim Mayer[1,2]
[1]RWTH Aachen University, GFE, Aachen, Germany, [2]Forschungszentrum Jülich GmbH, ER-C, Jülich, Germany, [3]Advanced Microelectronic Center Aachen, AMO GmbH, Aachen, Germany, [4]Forschungszentrum Jülich GmbH, IEK-1, Jülich, Germany, [5]University of Twente, Enschede, The Netherlands, [6]Forschungszentrum Jülich, IEK-12, Jülich, Germany

857 The reversible phase transition of Gd-doped ceria by in situ TEM

Dr Ke Ran[1,2,3], Dr Fanlin Zeng[4], Dr Lei Jin[2], Dr Stefan Baumann[4], Prof Wilhelm Meulenberg[4,5], Prof Joachim Mayer[1,2]
[1]RWTH Aachen University, GFE, Aachen, Germany, [2]Forschungszentrum Jülich GmbH, ER-C, Jülich, Germany, [3]Advanced Microelectronic Center Aachen, AMO GmbH, Aachen, Germany, [4]Forschungszentrum Jülich GmbH, IEK-1, Jülich, Germany, [5]University of Twente, Enschede, The Netherlands

858 In-Situ Manipulation of Growth Mechanisms in Ni-Seeded GaP Nanowires

Tianyi Hu[1,2], Dr. Yuanyuan Cao[1,2], Dr. Sara M. Franzén[2,3], Dr. Daniel Jacobsson[1,2,4], Dr. Michael S. Seifner[1,2], Prof. Maria E. Messing[2,3], Prof. Kimberly A. Dick[1,2,3]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]NanoLund, Lund University, Lund, Sweden, [3]Solid State Physics, Lund University, Lund, Sweden, [4]National Center for High Resolution Electron Microscopy, Lund University, Lund, Sweden

859 Vitamin A affects urothelial injury and regeneration in cyclophosphamide-induced cystitis

Teaching Asisstent Brina Dragar[1], Senior Research Fellow Simona Kranjc Brezar[2], Research Fellow Tadeja Kuret[1], Research Fellow Tanja Jesenko[2], Professor Maja Čemažar[2], Professor Rok Romih[1], Professor Mateja Kreft Erdani[1], Associate Professor Daša Zupančič[1]
[1]Institute of Cell Biology, Faculty of medicine, University of Ljubljana, Ljubljana, Slovenija, [2]Department of Experimental Oncology, Institute of OncologyOncology, Ljubljana, Slovenia

860 4D-STEM Optical Sectioning of Dopants in Diamond

Mr. Aidan Horne[1], Mr. Jacob Lewis[1], Mr. Emmanuel Tegegne[1], Dr. Peng Wang[1]
[1]University of Warwick, Coventry, United Kingdom

861 Correlative microscopy and spectroscopy of nanophotonic materials

Michael Foltýn[1], Petr Liška[1], Peter Kepič[1], Rastislav Motúz[2], Jaroslav Jiruše[2], Andrea Konečná[1], Vlastimil Křápek[1], Tomáš Šikola[1], Michal Horák[1]
[1]Brno University of Technology, Brno, Czech Republic, [2]TESCAN Group, R&D Department, Brno, Czech Republic

862 Birefringence analysis of hemozoin with surface plasmon microscopy towards malarial species distinction

Dr. Ipsita Chakraborty[1], Prof. Andreas Offenhäusser[1]
[1]Forschungszentrum Jülich GmBH, Jülich,, Germany

863 In situ examination of oxygen vacancy dynamics in epitaxial LaCoO3 thin films

Dr. Seung Jo Yoo[1], Mrs. Ji-Hyun Lee[1], Mr. Sang-Gil Lee[1], Dr. Hyung Joong Yun[1]
[1]Korea Basic Science Institute, Deajeon, Republic of Korea

864 Oscillatory redox behavior of nickel catalysts observed by operando SEM

Ms. Sci. Alexander Nitsche[1], Ms. Sci. Nico Radde[1], Dr. Ali Rinaldi[1], Prof. Dr. Marc Willinger[1]
[1]Department of Chemistry, School of Natural Sciences, TU Munich, Garching bei München, Germany

865 Structural Characterization of MOFs using Transmission Electron Microscopy and Software Innovation

Moussa Faye[1,2], Dr. Andrea Sala[1], Danilo Marchetti[1,2], Eloy P. Gomez-Oliveira[3], Natalia M. Padial[3], Carlos Martí-Gastaldo[3]
[1]Istituto Italiano di Tecnologia, Electron Crystallography, Center for Materials Interfaces, , Pisa, Italy, [2]University of Parma, Department of Chemistry, Life Sciences and Environmental Sustainability, Parma, Italy, [3]Functional Inorganic Materials Team, Instituto de Ciencia Molecular (ICMol), Paterna 46980, Spain

866 Transmission electron microscopy of dermal collagen using ethanolic phosphotungstic acid staining

Dr Astrid Obermayer[1], Dr Stefan Hainzl[2], Dr Ulrich Koller[2], Ao. Univ.-Prof. Dr. Walter Stoiber[1]
[1]Department of Environment & Biodiversity, University of Salzburg, Salzburg, Austria, [2]EB House Austria, Research Program for Molecular Therapy of Genodermatoses, Department of Dermatology and Allergology, University Hospital of the Paracelsus Medical University, Salzburg, Austria

867 From design to « operando » experiments in the SEM: application to battery studies

Dr Neelam Yadav[1], Mrs Melissa HERMANN ALba[1], Dr Morcrette Mathieu[1,2], Dr Carine Davoisne[1,2]
[1]LRCS, UMR CNRS 7314, Amiens, France, [2]Réseau sur le Stockage Electrochimique de l'Energie (RS2E), FR CNRS 3459, , France

868 High-Z Nanoparticle Tagging in Cryo-STEM for Localisation in Cryo-ET: Theory and Damage

Mr William Bowles[1,2,3], Dr Abner Velazco-Torrejon[1], Dr Siva Ramadurai[1], Dr Marcus Gallagher-Jones[1], Prof Angus Kirkland[1,4], Dr Alistair Siebert[2], Prof James Naismith[5], Dr Maud Dumoux[1]
[1]Structural Biology, Rosalind Franklin Institute, Didcot, United Kingdom, [2]Electron Biology Imaging Centre, Diamond Light Source, Didcot, United Kingdom, [3]Doctoral Training Centre, University of Oxford, Oxford, United Kingdom, [4]Department of Materials, University of Oxford, Oxford, United Kingdom, [5]Division of Structural Biology, Wellcome Trust Centre of Human Genomics, Oxford, United Kingdom

869 Combination of TEM, LM and micro-CT to image insects: the perspective of crop protection strategies

Nada Žnidaršič[1], Urban Bogataj[1], Polona Mrak[1], Katja Kunčič[1], Miloš Vittori[1], Primož Žigon[2], Jaka Razinger[2], Jerica Sabotič[3]
[1]University of Ljubljana, Biotechnical Faculty, Department of Biology, Ljubljana, Slovenia, [2]Agricultural Institute of Slovenia, Plant Protection Department, Ljubljana, Slovenia, [3]Jožef Stefan Institute, Department of Biotechnology, Ljubljana, Slovenia

870 High-resolution structural analysis of cation-mixed (Fe,Mn,Ni)PS3 van der Waals single crystals

Dr. Tatiana Smoliarova[1], B.Sc. Moritz Küster[1], Dr. Apoorva Chaturvedi[2], Prof. Edwin-Hang-Tong Teo[2], Prof. Michael Farle[1], Dr. Anna Semisalova[1]
[1]Faculty of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen, Duisburg, Germany, [2]Center for Programmable Materials, School of Materials Science and Engineering, Nanyang Technological University, Singapore, Singapore
871 STEM-EELS and Image simulations of inelastic spin-scattering of magnons in confined geometries
Julio Do Nascimento[1,2], Dr. Demie Kepaptsoglou[1,4], Prof. Quentin Ramasse[2,4], Prof. Vlado Lazarov[1,2]
[1]School of Physics, Engineering and Technology, University of York, York, United Kingdom, [2]York-JEOL Nanocentre, University of York, York, United Kingdom, [3]SuperSTEM Laboratory, SciTech Daresbury, Daresbury, United Kingdom, [4]School of Chemical and Process Engineering & School of Physics and Astronomy, University of Leeds, Leeds, United Kingdom
872 Microscopy of body surface sculpturing in terrestrial crustaceans
Ana Žuran[1], Dr. Miloš Vittori[1]
[1]Department of Biology, Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia
873 Toxic buffers used in microbial sample preservation for SEM can be replaced by PBS

Indra Banas[1], Noel Kleber[1], Dr. André Soares[1], Prof. Dr. Alexander Probst[1,2,3]
[1]Environmental Metagenomics, Research Center One Health Ruhr of the University Alliance Ruhr, Faculty of Chemistry, University of Duisburg-Essen, Essen, Germany, [2]Centre of Water and Environmental Research (ZWU), University of Duisburg-Essen, Essen, Deutschland, [3]Center of Medical Biotechnology (ZMB), University of Duisburg-Essen, Essen, Deutschland
874 Leveraging AutoScript for Cross-Platform Deep Learning Solutions in Electron Microscopy
Remco Geurts[1], Pavel Potocek[1], Noopur Jain[1], Ricardo Egoavil[1], Bert Freitag[1], Maurice Peemen[1], Yuri Rikers[1]
[1]ThermoFisher Scientific, Eindhoven, Netherlands
875 Exploring Role of Voltage-Gated Ion Channels in LGI1 Autoantibody-Induced Epilepsy: Insights from a Mouse Model
Dr Jacqueline Montanaro[1], Hana Stefanickova[1], Dr. Mary Muhia[1], Prof. Dr. med Christian Geis[2], Claudia Sommer[2], Josefine Sell[2], Prof. Dr. Hans-Christian Korna[3], Prof. Dr. Harald Prüß[3], Prof. Ryuichi Shigemoto[1]
[1]Institute of Science and Technology Austria (ISTA), , Klosterneuburg, Austria, [2]Department of Neurology, Section Translational Neuroimmunology, Jena University Hospital, Jena, Germany, [3]German Center for Neurodegenerative Diseases (DZNE), Berlin, Germany
876 Ultrastructural analysis of liver injury and regeneration after microcystin-LR intoxication in whitefish
PhD Natalia Szyrynska[1], Bogdan Lewczuk[1], Maciej Wozny[2], Pawel Brzuzan[2]
[1]Department of Histology and Embryology, Faculty of Veterinary Medicine, University of Warmia and Mazury in Olsztyn , , Poland, [2]Department of Environmental Biotechnology, Faculty of Geoengineering, University of Warmia and Mazury in Olsztyn, , Poland
877 Effect of chloroquine and naringin on the relationship between ER stress and mitochondria in trophoblasts
Research Associate Zehra Sezer[1]
[1]ISTANBUL UNIVERSITY-CERRAHPASA, Istanbul, Turkey
878 Understanding field evaporation sequences by in-situ correlative microscopy and simulation
Mohammed Ilhami[1], Prof. Williams Lefebvre[1], Prof. Francois Vurpillot[1]
[1]Groupe De Physique Des Matériaux, Saint Etienne Du Rouvray, France
879 FTIR-Imaging of a Tintoretto-Fresco

Dr. Maximilian Ries[1], Barbara Bravo[1], Eleonora Balliana[2]
[1]Thermo Fisher Scientific, , Germany/Italy/USA, [2]Ca' Foscari University of Venice, Venice, Italy
880 Raman-Imaging of the Strain-Distribution in Semiconductors
Dr. Maximilian Ries[1,2], Fabian Heisinger[2], Dr. Imad Limame[2]
[1]Thermo Fisher Scientific, , Germany/USA, [2]Technische Universität Berlin, Berlin, Germany
881 Towards electron beam shaping in an Ultrafast Transmission Electron Microscope
Valentin Rollo[1], Sebastien Weber[1], Arnaud Arbouet[1]
[1]CEMES - CNRS, Toulouse, France
882 Deconvolution of SBF-SEM images improves quality of data in volume electron microscopy
Amin Khosrozadeh[1], Adolfo Odriozola[1], Hans van der Voort[2], Yury Belyaev[3], Benoît Zuber[1]
[1]Institute of Anatomy, University of Bern, Bern, Switzerland, [2]Scientific Volume Imaging, Hilversum, The Netherlands, [3]Microscopy Imaging Center, University of Bern, Bern, Switzerland
883 In Situ SEM at Elevated Temperature for Materials Science
Ondřej Ambrož[1], Petr Horodyský[2], Jan Čermák[1], Patrik Jozefovič[1], Kateřina Sixtová[2], Šárka Mikmeková[1], Ondřej Lalinský[1]
[1]Institute of Scientific Instruments of the Czech Academy of Sciences, Brno, Czech Republic, [2]Crytur, Turnov, Czech Republic
884 Quantitative Super-Resolution Methods for Cryo-CLEM
Laura C. Zanetti-Domingues[1], Michael Hirsch[1], Lin Wang[1], Tara A. Eastwood[2], Karen Baker[2], Daniel P. Mulvihill[2], Sheena Radford[3], Jim Horne[3], Paul White[3], Dr Gea Van De Kerkhof[1], Benji Bateman[1]
[1]Central Laser Facility, Didcot, United Kingdom, [2]School of Biosciences, University of Kent, Canterbury, United Kingdom, [3]Astbury Centre for Structural Molecular Biology, School of Molecular and Cellular Biology, Faculty of Biological Science, University of Leeds, Leeds, United Kingdom
885 Characterization of a multiphase nucleus of spheroidal graphite cast irons by transmission electron microscopy techniques
PhD Alessandro Pugliara[1,2], PhD Lydia Laffont[1], PhD Claudie Josse[2], PhD Teresa Hungria[2], PhD Jacques Lacaze[1]
[1]CIRIMAT, Toulouse INP, Université Toulouse 3 Paul Sabatier, CNRS, Université de Toulouse, 4 allée Emile Monso, 31030, Toulouse, France, [2]Centre de microcaractérisation CASTAING, Université Toulouse 3 Paul Sabatier, Toulouse INP, INSA Toulouse, CNRS, Université de Toulouse, Espace Clément Ader, 3 Rue Caroline Aigle, 31400, Toulouse, France
886 Biorestoration Potential of Carbonatogenic Bacteria on Lithotypes: SEM and AFM characterization
Dr. Luca Buccini[1], Francesca Benedetti[2], Matilde Kratter[2], Francesco Mura[1,3], Anacleto Proietti[1], Pierfrancesco Atanasio[1], Angela Cirigliano[2], Marco Rossi[1,3], Teresa Rinaldi[1,2], Daniele Passeri[1,3]
[1]Department of Basic and Applied Sciences for Engineering (SBAI), La Sapienza University of Rome, Rome , Italy, [2]Department of Biology and Biotechnologies "Charles Darwin", Sapienza University of Rome, Rome, Italy, [3]CNIS-Center for Nanotechnology Applied to Industry of La Sapienza, La Sapienza University of Rome, Rome, Italy
887 Numerical study on high orbital angular momentum vortex electron beams in hafnium dioxide
Christian Bick[1], Dr. Dorothee Hüser[1]
[1]Physikalisch-Technische Bundesanstalt (PTB), Braunschweig, Germany
888 Free electron spectroscopy seen through the prism of quantum optics
Tom Fraysse[1], Hugo Lourenço-Martins[1]
[1]CEMES-CNRS, Toulouse, France
889 Correlation between manufacturing parameters, properties and microstructure in 2D-C/SiC composites

chiara gigante[1], Professor Stefano Poli, PhD Massimiliano Valle, Professor Simone Tumiati, phD Fabio Giacometti, Lorenzo Cavalli, Michela Arnoldi, phD Matteo Boiocchi, phD Yasir Akram, phD Michela Cantù
[1]Earth Science Department A. Desio, Milan, Italy

890 Analytical TEM of materials for gas sensing

Catalina-Gabriela Mihalcea[1,2], Corneliu Ghica[1], Adelina Stanoiu[1], Cristian-Eugen Simion[1], Daniela Ghica[1], Mariana Stefan[1], Simona Somacescu[3], Ioana-Dorina Vlaicu[1], Alexandra-Corina Iacoban[1]
[1]National Institute of Materials Physics, Atomistilor 405A, 077125, Romania, [2]Faculty of Physics, University of Bucharest, Atomistilor 405, 077125 , Romania, [3]"Ilie Murgulescu" Institute of Physical Chemistry, Romanian Academy, Spl. Independentei 202, 060021, Romania

891 Three-dimensional ultrastructure of ovine pinealocytes

Prof. Bogdan Lewczuk[1], Dr Natalia Szyrynska[1]
[1]Department of Histology and Embryology, Faculty of Veterinary Medicine, University of Warmia and Mazury in Olsztyn, , Poland

892 Mass microscopy allows for high throughput, high spatial resolution mass spectrometry imaging

Aljoscha Körber[1], Dr. Bryn Flinders[1], Frans Giskes[1], Prof. Ron M.A. Heeren[1], Dr. Ian G.M. Anthony[1]
[1]M4i / University of Maastricht, Maastricht, The Netherlands

893 A high-throughput compositional study of nanocrystals using a machine learning-assisted algorithm for STEM hyperspectral datasets

Mr. Basem Qahtan[1,3], Dr. Yurii P. Ivanov[1], Mr. Nikolaos Livakas[2,3], Mr. Francesco Di Donato[2], Prof. Liberato Manna[2], Dr. Giorgio Divitini[1]
[1]Electron Spectroscopy and Nanoscopy, Istituto Italiano di Tecnologia, Genoa, Italy, [2]Nanochemistry, Istituto Italiano di Tecnologia, Genoa, Italy, [3]Dipartimento di Chimica e Chimica Industriale, Università degli Studi di Genova, Genoa, Italy

894 Simulating iDPC tomography of CeO2 nanoparticles with experimentally realistic parameters and conditions

Miss Ella Kitching[1], Dr Thomas Slater[1]
[1]Cardiff Catalysis Institute, School of Chemistry, Cardiff University, Cardiff, United Kingdom

895 Microvessel and mitochondria changes in a mouse model of Alzheimer's disease

DVM PhD Stine Hasselholt[1,2], Cagla Cömert[2,3], Jesper Just[2,4], Peter Bross[3], Jens Randel Nyengaard[1,5], Brian Hansen[2], Leif Østergaard[2]
[1]Core Centre for Molecular Morphology, Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark, [2]Center of Functionally Integrative Neuroscience, Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark, [3]Research Unit for Molecular Medicine (MMF), Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark, [4]Dept. of Molecular Medicine (MOMA), Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark, [5]Dept. of Pathology, Aarhus University Hospital, Aarhus, Denmark

896 Cryo-EM Reveals RECQ5's Regulatory Role in RNAPII-Mediated Transcription

Karel Skubnik[1], Marek Sebesta[1], Jana Moravcova[1], Jiri Novacek[1], Richard Stefl[1,2]
[1]CEITEC–Central European Institute of Technology, Masaryk University, Brno, Czech Republic , [2]National Centre for Biomolecular Research, Masaryk University, Brno, Czech Republic

897 Surface tension of Au-catalysed GaAs-nanowires

Mr. Christopher Røhl Yskes Andersen[1,2], Mr. Marcus Tornberg[3,4,5], Mr. Daniel Jacobsson[3,4], Prof. Jonas Johansson[4,5], Prof. Kimberly A. Dick[3,4,5], Prof. Kristian S. Mølhave[2]
[1]Quantum DTU, Tech. Uni. of Denmark, Kgs. Lyngby, Denmark, [2]DTU Nanolab, Tech. Uni. of Denmark, Kgs. Lyngby, Denmark, [3]nCHREM, Lund Uni., Lund, Sweden, [4]NanoLund, Lund Uni., Lund, Sweden, [5]Solid State Physics, Lund Uni., Lund, Sweden

898 TEM observations of threading dislocations in gallium nitride under external stimuli

Mrs. Eva Kolibalova[1,2], Daniel Citterberg[2], Richard Gazdik[3], Petr Babor[2,3], Tomas Sikola[2,3], Miroslav Kolibal[2,3]
[1]CEITEC Nano, Brno University of Technology, Brno, Czech Republic, [2]CEITEC, Brno University of Technology, Brno, Czech Republic, [3]Institute of Physical Engineering, Brno University of Technology, , Czech Republic

899 Deep Learning Style Transfer for Elastic Image Registration of Visually Distinct Correlative Microscopy Images

Msc. Jan Čermák[1], PhD. Jiří Materna[2], MSc. Ondřej Ambrož[1], BSc. Patrik Jozefovič[1], PhD. Šárka Mikmeková[1]
[1]Institute of Scientific Instruments of the Czech Academy of Sciences, Brno, Czech Republic, [2]Machine Learning College, Brno, Czech Republic

900 Image Registration Based Navigation of Region of Interests in Volume Correlative Light and Electron Microscopy

Kohki Konishi[1,2], Guilherme Neves[2], Matthew Russell[2], Leanne Allison[2], Masafumi Mimura[3], Juan Burrone[2], Roland Fleck[2]
[1]Nikon U.K., Branch of Nikon Europe B.V., Surbiton, United Kingdom, [2]King's College London, London, United Kingdom, [3]Nikon Corporation, Tokyo, Japan

901 Microstructural Characterization of Electron Beam Welded Joints between EHEA and Austenitic Stainless Steel

M.Sc. Patrik Jozefovič[1], M.Sc. Jan Ronček[1], M.Sc. Ondřej Ambrož[1], M.Sc. Jan Čermák[1], Ph.D. Šárka Mikmeková[1]
[1]Institute of Scientific Instruments of the Czech Academy of Sciences, Brno, Czech Republic

902 Mechanisms of microglial responses to injury related focal ATP events

Dr Zsuzsanna Környei[1], Péter Berki[2,5,6], Dr Csaba Cserép[1], Dr Nikolett Lénárt[1], Dr Balázs Pósfai[1], Balázs Kalmár[1], Dr Kaikai He[3], Dr Ya Wang[4], Dr Zhaofa Wu[3], Dr Yulong LI[3], Dr Miao Jing[4], Dr Ádám Dénes[1]
[1]Momentum Laboratory of Neuroimmunology, Institute of Experimental Medicine, Budapest, Hungary, [2]János Szentágothai Doctoral School of Neuroscience, Semmelweis University, Budapest, Hungary, [3]State Key Laboratory of Membrane Biology, New Cornerstone Science Laboratory, School of Life Sciences, Peking University, Beijing , China, [4]Chinese Institute for Brain Research, Beijing , China, [5]Laboratory of Cerebral Cortex Research, Institute of Experimental Medicine, Budapest, Hungary, [6]Laboratory of Neuronal Network and Behaviour, Institute of Experimental Medicine, Budapest, Hungary

903 Complementary vEM approaches for ultrastructural changes during the development of D. melanogaster germline intercellular bridges

Dr Irina Kolotuev[1], Abigayle Elsbury[2], Caroline Kizilyaprak[1], Stephanie Pellegrino[2], Dr Lindsay Lewellyn[2]
[1]Faculté de Biologie et de Médecine, Université de Lausanne, Lausanne, Switzerland, [2]Department of Biological Sciences, Butler University, Indianapolis, USA

904 Investigation on photocorrosion of TiO2 during photoelectrochemistry process by electron microscopy together with operando ICP-MS

Dr. Yiqun Jiang[1], Dr. Martin Rabe[1], Dr. Ilias Efthimiopoulos[1], Prof. Christina Scheu[1], Dr. Siyuan Zhang[1]
[1]Max-Planck Institut für Eisenforschung GmbH, Düsseldorf, Germany

905 Advancing the real-time regime for virus self-assembly processes using liquid-electron microscopy

Professor Deb Kelly[1,2,3]

[1]Department of Biomedical Engineering, Penn State University, University Park, USA, [2]Center for Structural Oncology, Penn State University, University Park, USA, [3]Materials Research Institute, Penn State University, University Park, USA

906 Effects of corticosterone and amyloid beta on the corticosteroid receptors in organotypic brain slice cultures

Assistant Professor Merve Alaylıoglu[2], Professor ,PhD Selma Yilmazer[1], Professor PhD Erdinc Dursun[2], Professor PhD Duygu Gezen-Ak[2]
[1]Dept. of Medical Biology, Halic University, Faculty of Medicine, Istanbul, Turkey, [2]Brain and Neurodegenerative Disorders Research Laboratories, Department of Neuroscience, Institute of Neurological Sciences, Istanbul University- Cerrahpasa, Istanbul, , Turkey

907 Morphological investigation of periodic structures created by focused ion gallium beam

Márk Windisch[1,2], Dániel Selmeczi[3], Ádám Vida[2], Zoltán Dankházi[1]
[1]Eötvös Loránd University Department of Materials Physics, Budapest, Hungary, [2]Bay Zoltán Nonprofit Ltd. for Applied Research, Budapest, Hungary, [3]Semilab Semiconductor Physics Laboratory Co. Ltd., Budapest, Hungary

908 Cellulose-based Nanocomposites for Sensor Applications: Characterization and Performance Evaluation

Asst. Prof. Domagoj Belić[1], Assoc. Prof. Mislav Mustapić[1], M.Sc. Dino Galić[1], B.Sc. Barbara Špigl[1], B.Sc. Sara Stivi[1], Assoc. Prof. Željko Skoko[2], Ph.D. Teodoro Klaser[3], Assoc. Prof. Md Shahriar Al Hossain[4]
[1]Department of Physics, J. J. Strossmayer University of Osijek, Osijek, Croatia, [2]Department of Physics, Faculty of Science, University of Zagreb, Zagreb, Croatia, [3]Ruđer Bošković Institute, Zagreb, Croatia, [4]Faculty of Engineering, Architecture and Information Technology, The University of Queensland, Brisbane, Australia

909 Functionalization of Single-Walled Carbon Nanotubes Analyzed by Spatially-Resolved EELS

Dr Raul Arenal[1,2,3], Dr. Laurent Alvarez[4], Prof. Jean-Louis Bantignies[4]
[1]Instituto de Nanociencia y Materiales de Aragón, CSIC-Universidad de Zaragoza, Zaragoza, Spain., Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza. Zaragoza, Spain, Zaragoza, Spain, [3] Araid Foundation, Zaragoza, Spain , Zaragoza, Spain, [4]Laboratoire Charles Coulomb, U. Montpelier - CNRS, Montpellier, France

910 Electron beam manipulation with auto-ponderomotive potentials for interaction-free measurements

Msc. Franz Schmidt-Kaler[1], Mr. Michael Seidling[1], Mr. Robert Zimmermann[1], Mr. Nils Bode[1], Mr. Fabian Bammes[1], Mr. Lars Radtke[1], Mr. Peter Hommelhoff[1]
[1]AG Laserphysik, Friedrich-Alexander Universität Erlangen-Nürnberg, Germany

911 Microstructure and mechanical properties of AlCu thin films in a wide range of composition

Dániel Olasz[1,2], György Sáfrán[2], Noémi Szász[2], Tamás Kolonits[2], Nguyen Quang Chinh[1]
[1]Department of Materials Physics, Eötvös Loránd University, Budapest, Hungary, [2]Institute for Technical Physics and Materials Science, HUN-REN Centre for Energy Research, Budapest, Hungary

912 Enhanced Visible Light Photocatalytic Activity of Cu-Doped ZnO ALD Films Deposited on Porous Substrates

Assistant professor Ivna Kavre Piltaver[1,2], Robert Peter[1,2], Daria Jardas Babić[1,2], Matejka Podlogar[3], Aleš Omerzu[1,2], Krešimir Salamon[4]
[1]Faculty of Physics, University of Rijeka, Rijeka, Croatia, [2]Center for Micro- and Nanosciences and Technologies, Universitu of Rijeka, Rijeka, Croatia, [3]Jozef Stefan Institute, Ljubljana, Slovenia, [4]Ruđer Bošković Institute, Zagreb, Croatia

913 Examining dislocation and stacking faults within Hybrid MBE-Grown (110)-oriented RuO2 films

Dr Bita Pourbahari[1], Dr Seung Gyo Jeong[2], Sreejith Nair[2], Prof. Bharat Jalan[2], Prof. Nabil Bassim[1,3]

[1]Department of Materials Science and Engineering/ McMaster University, Hamilton, Canada, [2]Chemical Engineering and Materials Science, University of Minnesota−Twin Cities, Minneapolis, USA, [3]Canadian Centre for Electron Microscopy, McMaster University, Hamilton, Canada

914 On the accuracy of atomic-resolution DPC-STEM measurements

Rafael V. Ferreira[1,2], Sebastian Calderon V.[3], Prof. Paulo Ferreira[1,2,4]
[1]INL – International Iberian Nanotechnology Laboratory, Braga, Portugal, [2]Mechanical Engineering Department and IDMEC, Lisbon, Portugal, [3]Department of Materials Science and Engineering, Carnegie Mellon University, Pittsburgh, USA, [4]Materials Science and Engineering Program, The University of Texas at Austin, Austin, Portugal

915 Analysis of photon bunching in coherent cathodoluminescence

Mr Sotatsu Yanagimoto[1], Dr Naoki Yamamoto[1], Dr Takumi Sannomiya[1], Dr Keiichirou Akiba[1,2]
[1]Tokyo Institute of Technology, Nagatsuta, Midoriku, Yokohama,, Japan, [2]National Institutes for Quantum Science and Technology, Watanuki, Takasaki, Japan

916 The structural basis for energy extraction from air by Mycobacterium smegmatis

Ashleigh Kropp[1], Hari Venugopal[2], Chris Greening[1], Rhys Grinter[3]
[1]Department of Microbiology, Monash Biomedicine Discovery Institute, Monash University, Clayton, Australia, [2]Ramaciotti Centre for Cryo-Electron Microscopy, Monash University, Clayton, Australia, [3]Department of Biochemistry and Pharmacology, Bio21 Molecular Science and Biotechnology Institute, The University of Melbourne, Parkville, Australia

917 Simple and efficient three-dimensional reconstruction method of plant cells using transmission electron microscope

Ms. Haruka Aoki[1], Ms. Mizuki Matsuzaki[1], Mr. Hideo Nishioka[1], Ms. Chieko Hamamoto[1]
[1]JEOL Ltd., Akishima, Japan

918 Time-resolved TEM observation of CeO2 surface with electrostatic sub-framing system

Kanako Noguchi[1], Kazuki Yagi[2], Yuki Ninota[1], Dr. Takeshi Kaneko[3], Dr. Takeo Sasaki[1], Dr. Bryan W. Reed[2]
[1]JEOL Ltd, 3-1-2 Musashino Akishima, Japan, [2]IDES Inc., 4670 Willow Road, Suite 100, Pleasanton, USA, [3]JEOL USA Inc., 11 Dearborn Road, Peabody, USA

919 Continuous-flow LHe-cooling TEM sample holder with high stability at sub-10K and in situ biasing functionality

Penghan Lu[1], Denys Sutter[2], Dominik Biscette[2], András Kovács[1], Yan Lu[1], Joseph V. Vas[1], Michael Faley[1], Thibaud Denneulin[1], Damian Bucher[2], Amelia Estry[2], Johan Chang[2], Rafal E. Dunin-Borkowski[1]
[1]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, Jülich, Germany, [2]condenZero, Zürich, Switzerland

920 Revealing the origin of green light emission in Cs4PbBr6 by cathodoluminescence

Tetsuya Kubota[1], Mr. Sotatsu Yanagimoto[1], Prof. Hikaru Saito[1,2], Dr. Keiichirou Akiba[1,3], Prof. Ayumi Ishii[4], Prof. Takumi Sannomiya[1]
[1]Tokyo Institute of Technology, Yokohama, Japan, [2]Kyushu University, Kasuga, Japan, [3]National Institute for Quantum Science and Technology (QST), Takasaki, Japan, [4]Waseda University, Shinjuku, Japan

921 In-situ HAADF-STEM observation of phase transformation in microencapsulated Al-Cu-Si alloy

Dr Melbert Jeem[1], Dr Norihito Sakaguchi[1], Dr Takahiro Nomura[1]
[1]Faculty of Engineering, Hokkaido University, Sapporo, Japan

922 Microstructural characterization of Zr/ZrN and ZrN/ZrCN hard coatings using TEM

Dr. ANWAR UL HAMID[1]
[1]Core Research Facilities, King Fahd University of Petroleum & Minerals, Dhahran, Saudi Arabia

923 SEM Insights: Sample Temperature Evolution during EBSD

Christina Koenig[1], Yi-Chieh Yang[1], Senior Researcher Alice Bastos S. Fanta[1], Professor Joerg Jinschek[1]

[1]National Center for Nanofabrication and Characterisation (DTU Nanolab), Kgs. Lyngby, Denmark

924 Development of chopped scan control for beam blanking

Dr Grigore Moldovan[1]
[1]point electronic GmbH, Halle (Saale), Germany

925 Analysis of the cause of imperfect adhesion of cataphoretic coating using SEM and EDS method

Ph.D. Zuzana Koutova[1], Ing. Marie Novotna[1]
[1]MemBrain s.r.o., Stráž pod Ralskem, Czechia

926 TEM investigation of the defect structure in epitaxial corundum thin films

Claudio Bellani[1], Alberto Binetti[2], Wei-Fan Hsu[2], Simon Mellaerts[2], Koen Schouteden[2], Prof. Jean-Pierre Locquet[2], Prof. Jin Won Seo[1]
[1]Department of Materials Engineering, KU Leuven, Leuven, Belgium, [2]Department of Physics and Astronomy, KU Leuven, Leuven, Belgium

927 Automated Alignment Strategies for Integrating Cryo 3D-SIM and SXT Data

Dr Joaquín Otón[1], Dr Josué Gómez-Blanco[1], Dr Johannes Groen[1], Dr Ana Joaquina Pérez-Berná[1], Dr Eva Pereiro[1]
[1]ALBA Synchrotron - CELLS, Cerdanyola del Vallés, Spain

928 Reconstruction of Angstrom resolution exit-waves by the application of drift-corrected phase-shifting off-axis electron holography

Jonas Lindner[1], Ulrich Ross[2], Tobias Meyer[1], Victor Boureau[3], Michael Seibt[2], Christian Jooss[1,4]
[1]1 Institute of Materials Physics, University Goettingen, Goettingen, Germany, [2]2, 4th Institute of Physics – Solids and Nanostructures, University of Goettingen, Germany, [3]Interdisciplinary Center for Electron Microscopy, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, [4]4 International Center for Advanced Studies of Energy Conversion (ICASEC), University of Goettingen, Goettingen, Germany

929 The effects of TiC network microstructure on the mechanical properties of spark plasma sintered Al2O3

Umut Savaci[1], Salih Cagri Ozer[1], Eren Can[1], Yiğit Berkcan Harmankaya[1], Servet Turan[1,2]
[1]Eskisehir Technical University, Department of Materials Science and Engineering, Eskisehir, Turkey, [2]Ceramic Research Center, Eskisehir, Turkey

930 VitroJet: ice thickness control and measurement for time-efficient single particle structure determination3052

Rene Henderikx[1,2], Prof. Peter Peters[2], Dr. Bart Beulen[1]
[1]CryoSol-World, Weert, The Netherlands, [2]Maastricht University, Maastricht, The Netherlands

931 Direct observation of charge modulation in nanoprecipitates by 4D STEM

Dr. Juhyun Oh[1], Prof. Young-Woon Kim[1], Prof. Cheol-Woong Yang[2], Prof. Cheol-Hee Ahn[1], Prof Miyoung Kim[1]
[1]Department of Materials Science and Engineering, Seoul National University, Seoul, Korea, [2]Department of Materials Science and Engineering, Sungkyunkwan University, Suwon, Korea

932 In-situ TEM annealing of vanadium oxide thin films

Claudio Bellani[1], Simon Mellaerts[2], Koen Schouteden[2], Alberto Binetti[2], Wei-Fan Hsu[2], Prof. Jean-Pierre Locquet[2], Prof. Jin Won Seo[1]
[1]Department of Materials Engineering, KU Leuven, Leuven, Belgium, [2]Department of Physics and Astronomy, KU Leuven, Leuven, Belgium

933 Annular silicon drift detector for advanced EDS on SEM applications

Dr. Igor Németh[1], Dr. Yang Yang
[1]Bruker Nano GmbH, Berlin, Germany

934 Automatic signal clasification of the Low-Loss Region in Electron Energy Loss Spectroscopy

Vanessa Costa-Ledesma[1], Daniel del-Pozo-Bueno[1], Catalina Coll Benejam[2], Josep Nogués[2], Borja Sepulveda[3], Laura Bocher, Mathieu Kociak[4], Javier Blanco-Portals[1], Sònia Estradé Albiol[1], Francesca Peiró[1]
[1]LENS-MIND, Dept. d'Enginyeria Electrònica i Biomèdica and Institute of Nanoscience and Nanotechnology (IN2UB), Universitat de Barcelona, Barcelona, Spain, [2]2Catalan Institution for Research and Advanced studies, ICREA Academia, Bellaterra, Spain, [3]3Instituto de Microelectrónica de Barcelona (IMB-CNM, CSIC)Campus UAB, Bellaterra, Spain, [4]4Laboratoire de Physique des Solides (LSP), Microscopie électronique STEM, Orsay, France

935 Is iron a hidden culprit in Alzheimer's disease?

PhD Sowmya Sunkara[1], Dr Marlene Leoni[2], Dr Johannes Haybäck[2,3], Assoc. Prof. Dr Gerd Leitinger[1]
[1]Division of Cell Biology, Histology and Embryology, Gottfried Schatz Research Center, Medical University of Graz, Graz, Austria, [2]Diagnostics & Research Institute for Pathology, Medical University of Graz, Graz, Austria, [3]Tyrolpath Obrist Brunhuber GmbH, Zams, Austria

936 Cryo-FIB milling and Cryo-electron tomography of tissue biopsies: BBQ method

Dr Gediminas Gervinskas[1], Viola Oorschot[1], Hari Venugopal[1], Sylvain Trepout[1], A/prof Georg Ramm[1]
[1]Monash Ramaciotti Centre for Cryo EM, Clayton, Austalia

937 Investigation of the effects of production conditions and additives on the microstructure of PVDF-HFP membranes

Umut Savaci[1], Onur Ozgur Erkarslan[1]
[1]Department of Materials Science and Engineering, Eskisehir Technical University, Eskisehir, Turkey

938 In-situ observation and analysis of Ni-based catalysts for dry reforming of methane

Dr. Ayako Hashimoto[1,2], Mr. Yutain Han[1,2]
[1]National Institute for Materials Science, Tsukuba, Japan, [2]University of Tsukuba, Tsukuba, Japan

939 Combining synchrotron-based microCT with plasma FIB-SEM for targeted Volume EM

Dr Rachel Templin[1], Dr Denis Korneev[1], Dr Sergey Gorelick[1], Minyu Chan[1], A/prof Georg Ramm[1]
[1]Monash Ramaciotti Centre for Cryo EM, Clayton, Australia

940 Innovative Nanoanalytical Approaches for Lithium Metal Interface Analysis

Clementine Warres[1], Philipp Karl Albrecht[1], Dr. Tarek Lutz[1], Dr. Wilfried Nisch[1]
[1]NMI Natural and Medical Sciences Institute at the University of Tuebingen, Reutlingen, Germany

941 Mapping of phase separation of supramolecular protein assemblies by live-cell holotomography microscopy

Dr Orlando Marin[1], Dr Arina Dalaloyan[1], Professor Michael Elbaum[1]
[1]Weizmann Institute of Science, Rehovot, Israel

942 Differential axon terminal spread and synapse numbers amongst afferent neurons onto a locust's movement detector

Assoc. Prof. Dr Gerd Leitinger[1], Snjezana Radulovic[1], Dr Erin Cocks[3], Dr Claire Rind[3]
[1]Division of Cell Biology, Histology and Embryology, Gottfried Schatz Research Center, Medical University of Graz, Graz, Austria, [2]Electron Microscopy Research Services, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK, [3]Biosciences Institute, Faculty of Medical Sciences, Newcastle University, , Newcastle upon Tyne, UK

943 Advanced approaches for the analysis of micro- to nano-quartz particles using SEM, ESEM, FIB-SEM, SBF-SEM

Martin Olbert[1], Vilém Neděla[1], Josef Jirák[1], Jiří Hudec[1]
[1]Environmental electron microscopy group, Institute of Scientific Instruments of the CAS, v.v.i., Brno, Czech Republic

944 Enhanced sensitivity in label-free live-cell imaging using multi-pass stimulated Raman scattering microscopy

Joshua Reynolds[1], Dr. Shaun Burd[1], Tzu-Chieh (Jerry) Yen[1], Dr. Samsuzzoha Mondal[1,2], Dr. Soichi Wakatsuki[1,2], Dr. Mark Kasevich[1]
[1]Stanford University, Stanford, USA, [2]SLAC National Accelerator Laboratory, Menlo Park, USA
945 Resonant inelastic light scattering micro-spectroscopy to probe inter-moiré miniband excitations in twisted 2D semiconductors
Dr. Nihit Saigal[1,2], Dr. Lennart Klebl[3], Mr. Hendrik Lambers[1], Mr. Sina Bahmanyar[1], Mr. Veljko Antić[1], Prof. Dante Kennes[4,5], Prof. Tim Wehling[3,6], Prof. Ursula Wurstbauer[1,7]
[1]Institute of Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany, Münster, Germany, [2]EMBL Imaging Center, European Molecular Biology Laboratory, Meyerhofstr. 1, 69117 Heidelberg, Germany, Heidelberg, Germany, [3]Institute of Theoretical Physics, University of Hamburg, Notkestrasse 9, 22607 Hamburg, Germany, Hamburg, Germany, [4]Institute for Theory of Statistical Physics, RWTH Aachen University, and JARA Fundamentals of Future Information Technology, 52062 Aachen, Germany, Aachen, Germany, [5]Max Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, 22761 Hamburg, Germany, Hamburg, Germany, [6]The Hamburg Centre for Ultrafast Imaging, 22761 Hamburg, Germany, Hamburg, Germany, [7]Center for Soft Nanoscience (SoN), Busso-Peus-Str. 10, 48149 Münster, Germany, Münster, Germany
946 Investigation of earth-abundant photovoltaic material Zn3P2 nanostructures using electron microscopy
Aidas Urbonavicius[1,2], Dr. Sebastian Lehmann[2,3], Prof. Kimberly A. Dick[1,2,3], Dr. Simon Escobar Steinvall[1,2]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]NanoLund, Lund, Sweden, [3]Division of Solid State Physics, Lund University, Lund, Sweden
947 Engineering electron-electron interaction for advanced quantum metrology in electron microscopy

Phd Caterina Chiari[1,2], Prof Marco Beleggia[2], Dr Vincenzo Grillo[1]
[1]Centro S3, CNR - Istituto di Nanoscienze, Modena, Italy, [2]Department of Physics, Informatics and Mathematics, University of Modena, Modena, Italy
948 Human Tumor Microbiome Detection using Correlative Light and Electron Microscopy
Dr. Tali Dadosh[1], Dr. Smadar Levin-Zaidman[1], Dr. Deborah Nejman[2], Dr. Nancy Gavert[2], Prof. Ravid Straussman[2]
[1]Department of Chemical Research Support, Weizmann Institute of Science, Rehovot, Israel, [2]Department of Molecular Cell Biology, Weizmann Institute of Science, Rehovot, Israel
949 Mean inner potential measurement by correlated EFTEM and phase-shifting holography
Dr. Ing. Ulrich Ross[1], Dr. Christoph Flathmann[1], M.Sc. Jonas Lindner[2], Dr. Tobias Meyer[2], Dr. Andreas Beyer[3], Dr. Jürgen Belz[3], Prof. Dr. Kerstin Volz[3], Prof. Dr. Christian Jooss[2,4], Prof. Dr. Michael Seibt[1]
[1]4th Institute of Physics - Solids and Naonstructures, Georg-August-University Goettingen, Goettingen, Germany, [2]Institute of Materials Physics, Georg-August-University Goettingen, Goettingen, Germany, [3]Department of Physics and Materials Science Center, Philipps-University Marburg, Marburg, Germany, [4]International Center for Advanced Studies of Energy Conversion (ICASEC), Georg-August-University Goettingen, Goettingen, Germany
950 Atomic-scale imaging of local structure of layered Cu-Te phases
Dr. Habil. Andriy Lotnyk[1], Dr. Vladimir Roddatis[2], Nils Braun[1], Sonja Cremer[1], Dr. Hagen Bryja[1], Lennart Voss[3], Prof. Lorenz Kienle[3]
[1]Leibniz Institute of Surface Engineering (IOM), , Leipzig, Germany, [2]GFZ German Research Centre for Geosciences, Potsdam, Germany, [3]Institute for Materials Science, Faculty of Engineering, University of Kiel, Kiel , Germany

951 Cryo-EM structure of the HD6 defensin helical assembly
Dr. Roman Kamyshinsky[1], Lev Khmelnitsky[2], Rishir Kalepu[2], Dr. Nadav Elad[1], Prof. Deborah Fass[2]
[1]Department of Chemical Research Support, Weizmann Institute of Science, Rehovot, Israel, [2]Department of Chemical and Structural Biology, Weizmann Institute of Science, Rehovot, Israel
952 Temporal analysis of bone development in chick femur bone using label-free imaging
Miss Siddhi Chugh[1], Mr Jacob Kleboe[1,2], Dr Rahul S. Tare[3], Professor Richard OC Oreffo[2,3], Professor Sumeet Mahajan[1,2]
[1]School of Chemistry, Southampton, United Kingdom, [2]Institute of Life Sciences, Southampton, United Kingdom, [3]Human Development and Health, Southampton, United Kingdom
953 Study of nanolaser optical and structural properties at the nanometer scale
PhD Student Cléo Santini[1], Nika van Nielen[2], Pierre-Marie Coulon[3], Stéphane Vézian[3], Julien Brault[3], Philip A. Shields[5], Albert Polman[2], Benjamin Damilano[3], Christelle Brimont[4], Thierry Guillet[4], Sophie Meuret[1]
[1]CEMES, Toulouse, France, [2]AMOLF, Amsterdam, Netherlands, [3]CRHEA, Valbonne, France, [4]L2C, Montpellier, France, [5]University of Bath, , United Kingdom
954 New strategies of TEM sample preparation for the mitigation of carbon contamination
Dr. Julia Menten[1], Dr. Daniela Ramermann[1], Prof. Dr. Robert Schlögl[1,2], Dr. Walid Hetaba[1]
[1]Max Planck Institute for Chemical Energy Conversion, Mülheim an der Ruhr, Germany, [2]Fritz Haber Institute of the Max Planck Society, Berlin, Germany
955 Localisation of nanoparticles in whole cells using correlative cryo soft x-ray tomography and fluorescent microscopy
Mr Kenneth Fahy[1], Sergey Kapishnikov[1], Paul Sheridan[1], William Fyans[1], Fergal O'Reilly[1,2], Tony McEnroe[1]
[1]SiriusXT, Dublin , Ireland , [2]UCD Dublin, Dublin 4, Ireland
956 Sample preparation for correlative light, soft X-ray tomography, and cryo FIB-SEM imaging of biological cells
Director Imaging Applications Sergey Kapishnikov[1], Maryna Kobylynska[2,3], Prof. Roland A. Fleck[2,3], Malene Fog Lihme Olsen[4], Prof. Poul Erik Jensen[4], Dr Kenneth Fahy[1], Dr Paul Sheridan[1], Dr William Fyans[1], Dr Fergal O'Reilly[1,5,6], Tony McEnroe[1]
[1]SiriusXT Ltd., Dublin, Ireland, [2]Randall Centre for Cell and Molecular Biophysics, King's College London, London, United Kingdom, [3]Centre for Ultrastructural Imaging, King's College London, London, United Kingdom, [4]Department of Food Science, University of Copenhagen, Copenhagen, Denmark, [5]School of Physics, University College Dublin, Dublin, Ireland, [6]School of Biology and Environmental Sciences, University College Dublin, Dublin, Ireland
957 Improved conventional TEM sample preparation exploiting the birefringence of materials
Aleksander Brozyniak[1], Karin Stadlmann[1], Philipp Kürnsteiner[1], Heiko Groiss[1]
[1]Christian Doppler Laboratory for Nanoscale Phase Transformations, Center for Surface and Nanoanalytics, Johannes Kepler University Linz, Linz, Austria
958 TEM studies of polarization nanodomains in (BaTiO3/SrTiO3)10 superlattices on silicon
Dr Ines Haeusler[1], Valentin Väinö Hevelke[1], Adnan Hammud[2], Prof. Dr. Christoph Koch[3], Dong Jik Kim[1], Prof. Dr. Catherine Dubourdieu[1]
[1]Helmholtz-Zentrum Berlin für Materialien und Energie, Institute Functional Oxides for Energy Efficient Information Technology, 14109 Berlin, Germany, [2]Fritz-Haber Institut der Max-Planck-Gesellschaft, 14195 Berlin, Germany, [3]Humboldt-Universität zu Berlin, Department of Physics, 12489 Berlin, Germany
959 Charge Particle Optics Simulation Utilizing Hamiltonian Mechanics Perturbation Expansion and Boundary Elements Field Computation
Axel Lubk[1], Dr. Florent Houdellier[3], Dr. Heiko Müller[4], Dr. Stephan Uhlemann[4]

[1]IFW Dresden, Dresden, Germany, [2]TU Dresden, Dresden, Germany, [3]CEMES (CNRS), Toulouse, France, [4]CEOS GmbH, Heidelberg, Germany

960 Carbon nanoribbon formation by in-situ TEM manipulation of a C59N dithiolane derivative encapsulated into SWNTs

Dr Mario Pelaez-Fernandez[1,2,3], Dr Anastasios Stergiou[4], Dr Nikos Tagmatarchis[4], Dr Chris Ewels[5], Dr Raul Arenal[1,2,6]
[1]Instituto de Nanociencia y Materiales Aragón, CSIC-U. Zaragoza, Zaragoza, Spain, [2]Laboratorio de Microscopías Avanzadas, Universidad de Zaragoza, Zaragoza, Spain, [3]Unité Matériaux et Transformations (UMET UMR 8207), Univ Lille, Villeneuve d'Ascq, France, [4]Theoretical and Physical Chemistry Institute, National Hellenic Research Foundation, Athens, Greece, [5]Institut de Matériaux de Nantes Jean Rouxel, CNRS – Université de Nantes, , France, [6]ARAID Foundation, Zaragoza, Spain

961 Chemical and morphological stability study of copper oxide nanocubes in controlled and non-controlled atmospheres

Irene Piedra[1], Ramon Manzorro[1], M. Jose Guerra[1], Jose J. Calvino[1], Miguel Lopez-Haro[1], Ana B. Hungria[1]
[1]Departamento de Ciencias de los Materiales e Ingeniería Metalúrgica y Química Inorgánica, Facultad de Ciencias, Universidad de Cádiz, Campus Río San Pedro S/N, Puerto Real, 11510 Cádiz, Spain, Cádiz, Puerto Real, Spain

962 Comparison of the FMT assay with the Cell Painting approach in healthy patient derived fibroblasts.

Dr Tabea Hohensee[1], Dr Fredrik Edfeldt[1]
[1]Mechanistic and Structural Biology, Discovery Sciences, R&D, AstraZeneca, Gothenburg, Sweden

963 Robustness evaluation of electric field measurements via template matching in 4D-STEM

Alexis Wartelle[1], Matthew Bryan[2], Yiran Lu[1], David Cooper[2], Jean-Luc Rouvière[3], Martien den Hertog[1]
[1]Institut Néel, CNRS-UGA, Grenoble, France, [2]LETI, CEA, Grenoble, France, [3]MEM, IRIG, CEA, Grenoble, France

964 Molecular insights into the biogenesis of box H/ACA snoRNPs

Philipp Busse[1,2], Ana C. F. Paiva[1,2], Hugo Gizardin-Fredon[3], Dr. Paulo E. Santo[4], Dr. Xavier Manival[5], Dr. Hannah Oksannen[6], Dr. Sarah J. Butcher[6], Dr. Sarah Cianferani[3], Dr. Célia Plisson-Chastang[4], Dr. Tiago M. Bandeiras[1,2], Dr. Pedro M. F. Sousa[1,2]
[1]iBET, Instituto de Biologia Experimental e Tecnológica, Oeiras, Portugal, [2]Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal, [3]Institute du Medicament de Strasbourg, Strasbourg, France, [4]Universite de Toulouse, Toulouse, France, [5]Université de Lorraine, Vandoeuvre les Nancy , France, [6]University of Helsinki, Helsinki, Finland

965 Structural Analysis of COPI Pathway in Chlamydomonas reinhardtii

Dr. Grigory Tagiltsev[1], Dr Ricardo Righetto[2], Sagar Khavnekar[3,4], Dr. Ron Kelley[3], Dr. Xianjun Zhang[3], Dr. Abhay Kotecha[3], Dr. Benjamin Engel[2], Dr. Jürgen Plitzko[4], Dr. John Briggs[1]
[1]Department of Cell and Virus Structure, Max Planck Institute of Biochemistry, Martinsried, Germany, [2]Biozentrum, University of Basel, Basel, Switzerland, [3]Thermo Fisher Scientific, Eindhoven, The Netherlands, [4]Cryo-EM Technology group, Max Planck Institute of Biochemistry, Martinsried, Germany

966 Elimination of HCV replication machinery early after antiviral treatment with DAA monitored by multimodal microscopy

Dr. Victoria Castro[1], Gema Calvo[1], Ana Pérez-Berna[2], David Rogers[3], Stephen O'Connor[3], Sergey Kapishnikov[3], Paul Sheridan[3], Eva Pereiro[2], Kenneth Fahy[3], Dr. Pablo Gastaminza[1]
[1]Department of Molecular and Cellular Biology; Centro Nacional de Biotecnología-Consejo Superior de Investigaciones Científicas, Madrid, Spain, [2]ALBA Synchrotron Light Source, Cerdanyola del Valles, Spain, [3]SiriusXT, Dublin, Ireland

967 In-vivo DAB cytochemistry and high-pressure freezing to determine the source of the human cytomegalovirus envelope
Tim Bergner[1], Laura Cortez Rayas[2], apl. Prof. Jens von Einem[2], Dr. Clarissa Read[1]
[1]Central Facility for Electron Microscopy, Ulm University, Ulm, Germany, [2]Institute of Virology, Ulm University Medical Center, Ulm, Germany
968 Electron energy loss spectroscopy for differentiating of minerals polymorphs
Dr Vladimir Roddatis[1], Dr Elizaveta Kovaleva[1,2], Dr Marcin Syczewski[1], Anja Schreiber[1], Dr Richard Wirth[1], Prof Monica Koch-Müller[1]
[1]GFZ German Research Centre for Geosciences, Potsdam, Germany, [2]Department of Earth Sciences, University of the Western Cape, , South Africa
969 Transport of Intensity Phase Retrieval in the Presence of Intensity Variations and Unknown Boundary Conditions
Daniel Wolf[1], Radmila Kyrychenko[1], Max Herzo[1], Oleksandr Zaiets[1], Axel Lubk[1]
[1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany
970 Ultrastructural and chemical analysis of human Locus coeruleus using correlative microscopy and mass spectrometry
Zahraa BERRO[1], Dr Maria Angels Subirana[2], Dr Clementine Warres[3], Dr Tom Wirtz[1], Dr Tatjana Taubitz[1,4], Dr Jean-Nicolas Audinot[1], Dr Fabio A. Zucca[5], Dr Michel Mittelbronn[6,7], Dr Luigi Zecca[5], Dr Antje Biesemeier[1]
[1]Advanced Instrumentation for Nano-Analytics, Materials Research and Technology Department, Luxembourg Institute of Science and Technology, Esch-sur-Alzette, Luxembourg, [2]CNRS, Université de Pau et des Pays de l'Adour, E2S UPPA, Institut des Sciences Analytiques et de Physico-Chimie pour l'Environnement et les Matériaux (IPREM), 64000 Pau, France, [3]NMI Natural and Medical Sciences Institute at the University of Tübingen, 72770 Reutlingen, Germany, [4]Department of Structural Biochemistry, Max Planck Institute of Molecular Physiology, 44227 Dortmund, Germany, [5]Institute of Biomedical Technologies, National Research Council of Italy, Milan, Italy , [6]Luxembourg Centre for Systems Biomedicine, University of Luxembourg, 4362 Esch-sur-Alzette, Luxembourg , [7]Luxembourg Center of Neuropathology, National Center of Pathology, Laboratoire National de Santé, 3555 Dudelange, Luxembourg
971 Atomic-scale structure and defect evolution in Σ5 [001] tilt grain boundaries in copper
Dr. Rer. Nat Hui Ding[1], Anoosheh Akbari[2], Dr Esakkiraja Neelamegan[2], Prof. Sergiy Divinski[2], Prof. Gerhard Wilde[2], Prof. Christian H. Liebscher[1,3]
[1]Structure and Nano- / Micromechanics of Materials, Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany, [2]Institutre of Materials Physics, University of Münster, Münster, Germany, [3]Faculty of Physics and Astronomy and RC FEMS, Ruhr University Bochum, Bochum, Germany
972 Characterization of Precipitates in Petroleum Steels by Using Precession Electron Diffraction Technique
Umut Savaci[1], Servet Turan[1]
[1]Department of Materials Science and Engineering, Eskisehir Technical University, Eskisehir, Türkiye
973 Interpretable evaluation of STEM images of nanostructures via homology analysis
Mr. Ryuto Eguchi[1,2], Dr. Yu Wen[1,2], Dr. Ayako Hashimoto[1,2]
[1]National Institute for Materials Science, Tsukuba, Japan, [2]University of Tsukuba, Tsukuba, Japan
974 Strategies for Multimodal Image Data Transformation to a Common Format for Cloud Integration and Visualization
Phd Rafael Camacho[1], PhD Jens Berndtsson[1], PhD Massimo Micaroni[1], PhD Karl Zhang[1], PhD Julia Fernandez-Rodriguez[1]
[1]Center for Cellular Imaging, Core Facilities, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden

975 Phase-controlled formation of NixPy catalyst using environmental TEM for potential application in CO2 reduction
Dr. Kshipra Sharma[1,2], Mr. Tianyi Hu[1,2], Prof. Kimberly A. Dick[1,2]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]Nanolund, Lund University, Lund, Sweden
976 Evaluation of inflammation and free fatty acid metabolism as biomarkers in female patients
Assoc.prof.dr. Pınar Köroğlu[1], Sultan Üzümcüoğlu[2], Muhammed Melik Anşin[2], Prof.Dr. Ulun Uluğ[3]
[1]Halic University, Faculty of Medicine, Department of Histology and Embryology , Istanbul, Turkey, [2]Halic University, Faculty of Medicine, Istanbul,, Turkey, [3]Halic University, Faculty of Medicine, Department of Obstetrics and Gynecology, , Turkey
977 The Healing Effect Of Ferulic Acid in Monosodium Glutamate-Induced Liver Injury
Student Seda Sezer[1,2], Anıl Can[1,2], Assoc. Dr. Merve Açıkel Elmas[1], Assoc. Dr. Meltem Kolgazi[3], Prof. Dr. Serap Arbak[1]
[1]Department of Histology and Embryology, School of Medicine, Acibadem Mehmet Ali Aydinlar University, Istanbul, Turkey, [2]Department of Histology and Embryology, Institute of Health Sciences, Acibadem Mehmet Ali Aydinlar University, Istanbul, Turkey, [3]Department of Physiology, School of Medicine, Acibadem Mehmet Ali Aydinlar University , Istanbul , Turkey
978 In situ growth and phase engineering of manganese arsenide nanostructures in environmental TEM
Hedda Christine Soland[1,2], Mikelis Marnauza[1,2], Pau Ternero[2,3], Professor Kimberly A. Dick[1,2]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]NanoLund, Lund University, Lund, Sweden, [3]Solid State Physics, Lund University, Lund, Sweden
979 Advanced image analysis techniques to support and streamline cell manufacturing
Dr Fuad Mosis[1]
[1]bit.bio, Babraham Research Campus,, United Kingdom
980 Ultra-low voltage SEM observation for battery materials
Ph.D. Yutaka Nagaoka[1], Dr. Yoichiro Hashimoto[1], Mr. Toru Aiso[1], Mr. Shuhei Yabu[2], Mr. Masahiro Sasajima[3]
[1]Solution Development Dept., Hitachi High-Tech Corporation, Hitachinaka, Japan, [2]Electron Microscope Systems Design Dept., Hitachi High-Tech Corporation, Hitachinaka, Japan, [3]Software Design Dept., Hitachi High-Tech Corporation, Hitachinaka, Japan
981 Structural Study of Polyphasic Mixtures Using 3d Electron Diffraction:A Case Study of Oxyresveratrol
Ms Vincentia Emerson Agbemeh[2]
[1]Electron Crystallography, Center for Materials Interfaces, Istituto Italiano di Tecnologia, Pontedera, Italy, [2]Department of Chemistry, Life Sciences and Environmental Sustainability, University of Parma, Parma, Italy
982 Neuroprotective Effects of Bromelain in Peripheral Nerve Injuries: A Rat Sciatic Nerve Crush Injury Model
DR. ONUR AKSOY[3], DR. ILKER USCETIN[3], ASSOC. PROF. SAMED OZER[2], ASSOC. PROF. MERVE ACIKEL ELMAS[1], BIO. GOKCEN OZGUN[4], BIO. SEDA SEZER[5], Prof. Dr Serap Arbak[1]
[1]DEPARTMENT OF HISTOLOGY AND EMBRYOLOGY ACIBADEM MEHMET ALI AYDINLAR UNIVERSITY SCHOOL OF MEDICINE, ISTANBUL, TURKEY, [2]Animal Application and Research Center, Acibadem Mehmet Ali Aydinlar University, ISTANBUL, TURKEY, [3]Prof Dr Cemil Tascioglu City Hospital, Department of Plastic and Reconstructive Surgery, ISTANBUL, TURKEY, [4]Institute of Health Sciences, Department of Biotechnology, Acibadem Mehmet Ali Aydinlar University, ISTANBUL, TURKEY, [5]Institute of Health Sciences, Department of Histology and Embryology Acibadem Mehmet Ali Aydinlar University, ISTANBUL, TURKEY

983 Establishment of 30mm diameter milling and curtaining effect reduction by large area planar surface milling
Mr. Yuji Hasebe[1], Munehiro Kozuka[1], Takashi Sueyoshi[1], Akihiro Tanaka[1], Tatsuhito Kimura[1], Tamae Omoto[1], Yasuaki Yamamoto[1], Koji Todoroki[1], Hiroshi Onodera[1]
[1]JEOL Ltd, Akishima city/ Musahino3-1-2, Japan
984 Characterization of casting inclusions in superalloys by BSE and EDS
Prof. Dr. Dragan Rajnović[1]
[1]Faculty of Technical Sciences, University of Novi Sad, Novi Sad, Serbia
985 Thin Film Phase Plates for Cryo TEM: Fabrication,
and Characterization Using Electron Holography
Marcus Hufe[1], Mads Larsen[1], Prof. Stephan Keller[1], Prof. Marco Beleggia[1,2], Associate Professor Paul Kempen[1]
[1]Technical University of Denmark, Copenhagen, Denmark, [2]University of Modena and Reggio Emilia, Modena, Italy
986 PFIB and SEM engineering of luminescent centres in hBN
Diane-Pernille Bendixen-Fernex De Mongex[2], Mr Mihai Vlad Ursta Anghel[1], Mr Amedeo Carbone[2,3], Associate Professor Nicolas Leitherer-Stenger[2,3], Senior Researcher Shima Kadkhodazadeh[1,6], Professor Thomas Willum Hansen[1]
[1]DTU Nanolab, Kgs. Lyngby, Denmark, [2]DTU Electro, Kgs. Lyngby, Denmark, [3]NanoPhoton – Center for Nanophotonics, Kgs. Lyngby, Denmark
987 Non-toxic clearing and labeling with fluorescent REAfinityTM antibodies for enhanced 3D visualization of tissues
Msc Kevin Bigott[1]
[1]Miltenyi Biotec B.V. & Co. KG, Cologne, Germany
988 Deformation of steel chips due to machining
Dr. Sabine Schwarz[1], Univ.Ass. Dipl.-Ing. Christian Baumann[2]
[1]University Service Centre for Transmission Electron Microscopy (USTEM), TU Wien, Vienna, Austria, [2]Institute of Production Engineering and Photonic Technologies, Vienna, Austria
989 Characterization of Cu doped zeolite by MicroED and electron ptychography
Mr. Masahiko Shimizu[1], Dr. Katsuaki Nakazawa[2], Dr. Kazutaka Mitsuishi[2], Dr. Hajime Matsumoto[1], Dr. Hisashi Shima[1], Dr. Takahiko Takewaki[1], Dr. Ayako Hashimoto[2,3]
[1]Mitsubishi Chemical corporation, Yokohama, Japan, [2]National Institute for Materials Science, Tsukuba, Japan, [3]University of Tsukuba, Tsukuba, Japan
990 From volume electron microscopy datasets to segmentation models, feature quantification, and data reuse
Dr. Ilya Belevich[1], Kirk Czymmek[2], Johanna Bischof[3], Aastha Mathur[3], Lucy Collinson[4], Eija Jokitalo[1]
[1]University of Helsinki, Helsinki, Finland, [2]Donald Danforth Plant Science Center, Saint Louis, USA, [3]Euro-BioImaging ERIC Bio-Hub, EMBL, Heidelberg, Germany, [4]Francis Crick Institute, London, UK
991 Temporal characterization of femtosecond electron pulses inside ultrafast scanning electron microscope
Kamila Moriova[1], Martin Kozak[1]
[1]Faculty of Mathematics and Physics, Charles University, Prague,
992 Optimizing optical STEM detection for faster acquisition speeds in scanning electron microscopy
Arent J. Kievits[1], Monika Molnar[1], Jacob P. Hoogenboom[1]
[1]Department of Imaging Physics, Delft University of Technology, Delft, The Netherlands
993 HR-EBSD Analysis of High-Entropy Alloys: Understanding the Role of Alloying Elements in Mechanical Performance

Mr Pedro Henrique Fernandes Oliveira[1,2], Mr Julio Spadotto[2,3], Mr Edward Pickering[2,3], Mr Francisco Coury[1], Mr Claudemiro Bolfarini[1]
[1]Federal University of Sao Carlos, Sao Carlos, Brazil, [2]The University of Manchester, Manchester, United Kingdom, [3]Henry Royce Institute, Manchester, United Kingdom

994 SEM-Cathodoluminescence Imaging and Spectroscopy - Applications in Archeology and Life Science

Dr. Ifat Kaplan-Ashiri[1]
[1]Electron Microscopy Unit, Department of Chemical Research Support, Weizmann Institute of Science, Rehovot, Israel

995 Detection of quasicrystalline symmetries in electron diffraction data

Oskar Ryggetangen[1], Dr. Ruben Bjørge[2], Dr. Sigurd Wenner[2], Prof. Randi Holmestad[1]
[1]Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway, [2]Department of Materials and Nanotechnology, SINTEF Industry, Trondheim, Norway

996 2D and 3D Oxidation State Mapping in FeO/Fe3O4 Nanocubes Using the Fe-M2,3 EELS Edge

Dr Mario Pelaez-Fernandez[1,2,3], Daniel del-Pozo-Bueno[4,5], Dr Maya Marinova[6], Dr Adrien Teurtrie[1], Prof. Hugues Leroux[1], Prof. Francesca Peiró[4,5], Prof. Sonia Estradé[4,5], Dr Francisco De la Peña[1]
[1]Unité Matériaux et Transformations (UMET UMR 8207), Université de Lille, Bâtiment C6, Cité Scientifique, Villeneuve d'Ascq, France, [2] Instituto de Nanociencia y Materiales de Aragon (INMA), CSIC-U. de Zaragoza, Zaragoza, Spain, [3]Laboratorio de Microscopias Avanzadas, Universidad de Zaragoza, Zaragoza, Spain, [4]LENS-MIND, Departament d'Enginyeria Electrònica i Biomèdica, Universitat de Barcelona, Barcelona, Spain, [5]Institute of Nanoscience and Nanotechnology (IN2UB), Universitat de Barcelona, , Spain, [6]Univ. Lille, FR 2638-IMEC-Institut Michel-Eugène Chevreul, , France

997 Ultrafast Microbeam Electron Diffraction at 15-keV

Johannes Otto[1,2,3], Leon Brauns[1,2], Rudolf Haindl[1,2], Jan Gerrit Horstmann[1,2], Armin Feist[1,2], Murat Sivis[1,2], Claus Ropers[1,2,3]
[1]Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany, [2]4th Physical Institute, University of Göttingen, Göttingen, Germany, [3]Max Planck School of Photonics , ,

998 Contribution of residual gas and surface contaminants to contamination growth on irradiated samples

Arne Schwartz[1], Dr. Erich Müller[1], TT.-Prof. Dr.-Ing. Yolita Eggeler[1,2]
[1]Laboratory for Electron Microscopy, Karlsruhe Institute of Technology (KIT), Karlsruhe, , [2]3DMM2O - Cluster of Excellence (EXC-2082/1 – 390761711), Karlsruhe Institute of Technology (KIT), Karlsruhe,

999 Measurement of electrostatic fields in Ge-doped AlGaN structures by off-axis electron holography

Phd Student Alexis Palais[1], Director of Research David Cooper[1], Senior Researcher Eva Monroy[2], Director of Research Bérangère Hyot[1]
[1]CEA-LETI, Grenoble, France, [2]CEA, Grenoble INP, IRIG, PHELIQS, Grenoble, France

1000 PolSpec – broadband cost-effective hyperspectral imaging

Huihui Liu[1], Sunil Kumar[1,2], Edwin A Garcia Castano[1], Paul French[1,2]
[1]Physics Department, Imperial College London, SW7 2AZ, , UK, [2]Francis Crick Institute, 1 Midland Road, NW1 1AT, , UK

1001 Dynamics of an industrial Cu/ZnO catalyst revealed by operando TEM

Maxime Boniface[1], Thomas Götsch[1], Jinhu Dong[1], Elias Frei[1], Annette Trunscke[1], Robert Schlögl[1,2], Beatriz Roldàn Cuenya[3], Thomas Lunkenbein[1]
[1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Department of Inorganic Chemistry, Berlin, Germany, [2]Department of Heterogeneous Reactions, Max-Planck-Institute for Chemical Energy

Conversion, Mülheim, Germany, [3]Department of Interface Science, Fritz Haber Institute of the Max Planck Society, , Berlin, Germany

1002 Structural and Electrical Characterization of $Hf_{0.5}Zr_{0.5}O_2$ Thin Films Crystallized by Rapid Thermal Annealing

Dr Jucheol Park[1], Miss Yeong Gyeong Park[1], Dr Min-Ho Kang[2], Mr Myung-Keun Lee[2], Mr Moon Seop Hyun[2]
[1]Gumi Electronics & Information Technology Research Institute (GERI), Gumi-si, Republic of Korea, [2]Department of Nano-process, National NanoFab Center (NNFC), Daejeon, Republic of Korea

1003 Investigating the photoelectronic properties of MoS2 thin layer with ITO nanoparticles using photoluminescence and cathodoluminescence

Mr Andrea Cicconardi[1,2], Dr Andrea Griesi[1], Dr Gunnar Kusch[4], Dr Silvia Dante[1], Prof Rachel Oliver[4], Dr Ilka Kriegel[1,3], Dr Giorgio Divitini[1]
[1]Istituto Italiano di Tecnologia, Genova, Italy, [2]University of Genova, Genova, Italy, [3]Istituto Italiano di Tecnologia, Turino, Italy, [4]University of Cambridge, Cambridge, United Kingdom

1004 Electron tomography of radiation sensitive nanocomposites for additive manufacturing

Dr. Luisa M. Valencia[1], Dr. Jesús Hernández-Saz[2], Dr. Natalia Fernández-Delgado[1], Prof. Sergio I. Molina[1], Prof. Miriam Herrera[1]
[1]Departamento de Ciencia de los Materiales e Ingeniería Metalúrgica y Química Inorgánica, IMEYMAT, Facultad de Ciencias, Universidad de Cádiz, Campus Río San Pedro s/n, Puerto Real, Spain, [2]Departamento de Ingeniería y Ciencia de los Materiales y del Transporte, Universidad de Sevilla, Avda. Camino de los Descubrimientos s/n, Sevilla, Spain

1005 Hyperspectral CT allows for non-destructive elemental imaging in museum specimen

Henrik Lauridsen[1], Daniel Klingberg Johansson[2], Christina Carøe Ejlskov Pedersen[3], Kasper Hansen[3], Michiel Krols[4], Kristian Murphy Gregersen[5], Julie Nogel Jæger[5], Catherine Jane Alexandra Williams[6], Ditte-Mari Sandgreen[7], Aage Kristian Olsen Alstrup[1,8], Mads Frost Bertelsen[9,10], Peter Rask Møller[2]
[1]Department of Clinical Medicine, Aarhus University, , Denmark, [2]Natural History Museum of Denmark, University of Copenhagen, , Denmark, [3]Department of Forensic Medicine, Aarhus University, , Denmark, [4]TESCAN XRE, , Belgium, [5]Institute of Conservation, Royal Danish Academy, , Denmark, [6]Department of Animal and Veterinary Sciences, Aarhus University, , Denmark, [7]Givskud Zoo-Zootopia, , Denmark, [8]Department of Nuclear Medicine & PET, Aarhus University Hospital, , Denmark, [9]Center for Zoo and Wild Animal Health, Copenhagen Zoo, , Denmark, [10]Department of Veterinary Clinical Sciences, University of Copenhagen, , Denmark

1006 FIB-SEM/microtoming prepared Cross Section of a Stone Wool Fiber enabling (S)TEM investigation

Phd Student Krestine Hofstedt Rasmussen[1,2], Ph.D Denis V. Okhrimenko[2], Ph.D Louise J. Belmonte[2], Ph.D Dorthe B. Ravnsbæk[3], Ph.D Espen D. Bøjesen[1]
[1]Interdisciplinary Nanoscience Center, Aarhus University, Aarhus, Denmark, [2]ROCKWOOL A/S, Hedehusene, Denmark, [3]Department of Chemistry, Aarhus University, Aarhus, Denmark

1007 The importance of an open camera system demonstrated with wide-ranging applications of MerlinEM detector

Dr Matus Krajnak[1], Dr Gearoid Mangan[1]
[1]Quantum Detectors Ltd, Harwell Oxford, United Kingdom

1008 2D and 3D EELS Analyses on the Low-Energy Core-Loss Edges in Beam-sensitive Ryugu Asteroid Samples

Dr Mario Pelaez-Fernandez[1,2,3], Dr Maya Marinova[4], Dr Adrien Teurtrie[1], Dr Simon Hettler[1], Sylvain Laforet[1], Dr Corentin Le Guillou[1], Prof. Hugues Leroux[1], Dr Raul Arenal[2,3], Dr Francisco De la Peña[1]
[1]Unité Matériaux et Transformations (UMET UMR 8207), Université de Lille, Bâtiment C6, Cité Scientifique, Villeneuve d'Ascq, France, [2]Instituto de Nanociencia y Materiales de Aragon (INMA),

CSIC-U. de Zaragoza, Zaragoza, Spain, [3]Laboratorio de Microscopias Avanzadas, Universidad de Zaragoza, Zaragoza, Spain, [4]Univ. Lille, FR 2638-IMEC-Institut Michel-Eugène Chevreul, Lille, France

1009 Setting up fringe-free imaging for SPA on Talos Arctica and Titan Krios microscopes

Dr Nadav Elad[1], Dr Roman Kamyshinsky[1]
[1]EM Unit, Department of Chemical Research Support, Weizmann institute of science, Rehovot, Israel

1010 Imaging ultrafast spin dynamics at the nanometer scale

Dr Gaolong Cao[1], Sheng Jiang[2], Yuzhu Fan[1], Johan Åkerman[3], Jonas Weissenrieder[1]
[1]Royal Institute of Technology (KTH), Stockholm, Sweden, [2]South China University of Technology, Guangzhou, China, [3]University of Gothenburg, Gothenburg, Sweden

1011 Sequential tilting 4D-STEM for reliable electric field mapping across junctions

Christoph Flathmann[1], Ulrich Ross[1], Andreas Beyer[2], Jürgen Belz[2], Kerstin Volz[2], Michael Seibt[1], Tobias Meyer[3]
[1]4th Physical Institute, Georg-August-University Goettingen, Göttingen, Germany, [2]Department of Physics and Materials Science CenterPhilipps-University Marburg, Marburg, Germany, [3]Institute of Materials Physics, Georg-August-University Goettingen, Göttingen, Germany

1012 A validation methodology for size and shape measurement of nanoplastics by transmission electron microscopy

Charlotte Wouters[1], Denrich Morales[1], Khariklia Tsilikas[1], Eveline Verleysen[1], Jan Mast[1]
[1]Trace Elements and Nanomaterials, Sciensano, Brussels, Belgium

1013 TEM 3D Spectroscopic Imaging for Catalytic Activity Evaluation

Dr. Hionsuck BAIK[1], Dr. Taekyung KIM[1], Dr Yongju Hong[2], Dr. Kwangyeol LEE[3]
[1]Korea Basic Science Institute, Seoul, South Korea, [2]Korea Institute Science of Technology, Seoul, South Korea, [3]Korea University, Seoul, South Korea

1014 Large-volume cryoEM sample preparation for the investigation of the plant-microbiome interaction

Janine Liedtke[1], PhD. Jana Moravcová[2], PhD. Ing. Pavel Křepelka[2], Marije van Son[3], PhD Jirka Nováček[2], Dr. Vasilis Kokkoris[3], Prof. Dr. Thomas S. Shimizu[4], Prof. Dr. Toby Kiers[3], Prof. Dr. Ariane Briegel[1]
[1]Microbial Sciences, Institute of Biology Leiden (IBL), Leiden University, Leiden, Netherlands, [2]Cryo-Electron Microscopy and Tomography Core Facility, CEITEC, Masarykova University, Brno, Czech Republic, [3]Amsterdam Institute of Life and Environment (A-LIFE), Vrije Universiteit Amsterdam, Amsterdam, Netherlands, [4]Physics of Behavior, AMOLF Institute, Amsterdam, Netherlands

1015 The Development of Japanese ceramic ware (pottery and porcelain) Technology as Revealed by EPMA

Dr Rie WAKIMOTO[1], Dr Susumu KAKUBUCHI[2], Dr Sergei Matveev[3]
[1]JEOL Ltd., Musashino Akishima, Japan, [2]SAGA University, SAGA , Japan, [3]JEOL (GERMANY) GmbH, Gute Aenger, Germany

1016 Relative thickness study of TEM samples

Dr Sandra Drev[1], Petra Drnovšek[1], Dr Miran Čeh[1,2]
[1]Center for Electron Microscopy and Microanalysis, Jožef Stefan Institute, Ljubljana, Slovenia, [2]Department for Nanostructured Materials, Jožef Stefan Institute, Ljubljana, Slovenia

1017 IN-SITU SYNTHESIS OF FexPy NANOPARTICLES

PhD student Azemina Kraina[1,2], Tianyi Hu[1,2], Pau Ternero[2,3], Professor Kimberly A. Dick[1,2]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]NanoLund, Lund University, Lund, Sweden, [3]Solid State Physics, Lund University, Lund, Sweden

1018 Metal-Organic Chemical Vapor Deposition in a Transmission Electron Microscope

Dr Daniel Jacobsson[1,2,3], Dr Marcus Tornberg[1,2,3], Dr Carina, B. Maliakkal[1,2,3], Prof Reine Wallenberg[1,2,3], Prof Kimberly, A. Dick[1,2,3]

[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]NanoLund, Lund University, Lund, Sweden, [3]National Centre for High Resolution Electron Microscopy, Lund University, Lund, Sweden

1019 Quantitative Elemental Mapping Of Bimetallic Nanoparticles From Atomic Scale STEM-HAADF Images

Adrien Moncomble[1], Damien Alloyeau[1], Guillaume Wang[1], Nathaly Ortiz-Peña[1], Hakim Amara[1,2], Riccardo Gatti[2], Maxime Moreaud[3], Christian Ricolleau[1], Jaysen Nelayah[1]
[1]Université Paris Cité / CNRS, Paris, France, [2]Université Paris-Saclay / CNRS, Chatillon, France, [3]IFP Énergies Nouvelles, Solaize, France

1020 Leveraging FIB-SEM with Integrated ToF-SIMS for Comprehensive Characterization of Lithium-Ion Battery Materials

Dr. Tomáš Šamořil[1], Jiří Dluhoš[1], Jiří Honč[1], Dr. Tan Sui[2], Dr. Xuhui Yao[3]
[1]TESCAN GROUP, a.s., Brno, Czech Republic, [2]University of Surrey, Guildford Surrey, UK, [3]National Physical Laboratory, Teddington, UK

1021
Morphological characterization of the electric field aligned block copolymers containing liquid crystal moiety

Monika Król[1], Isaac Álvarez Moisés[2], Janne Ruokolainen[1], Jean-François Gohy[2]
[1]Aalto University, Espoo, Finland, [2]Université catholique de Louvain, Louvain-la-Neuve, Belgium

1022 TEM investigation of AlN-Cu(O) with variable amounts of copper

PL Martin[1], PY Jouan[1], Nicolas Gautier[1], M Richard-Plouet[1], Dr Valerie Brien[1]
[1]Nantes université, CNRS, Institut des Matériaux de Nantes Jean Rouxel, IMN, F-44000 Nantes, France

1023 FRET and TIRF microscopy for single molecule characterisation of synergistic antimicrobial peptides in artificial bilayers

Miss Hannah Baird[1], Dr William David Jamieson[1], Dr Oliver Castell[1]
[1]School of Pharmacy and Pharmaceutical Sciences, Cardiff University, Cardiff, United Kingdom

1024 Structural and Compositional Investigation of Ag-Incorporated CsPbBr3 Nanocrystal Heterostructures

Dr Sirous Khabbaz Abkenar[1], Ms. Anna Cabona[2,3], Mr. Basem Ameen Ahmed Qahtan[1,3], Dr. Stefano Toso[2], Dr. Andrea Griesi[1], Prof. Liberato Manna[2], Dr. Giorgio Divitini[1]
[1] Istituto Italiano di Tecnologia, Electron Spectroscopy and Nanoscopy, Genova, Italy, [2]Istituto Italiano di Tecnologia, Nanochemistry, Genova, Italy, [3]Dipartimento di Chimica e Chimica Industriale, Università degli Studi di Genova, Genova, Italy

1025 A novel pipeline to elucidate the adaptation response to the G2/M DNA damage checkpoint

Doctor Ambra Dondi[1], Ms. Sara Spreafico[1], Dr. Simona Rodighiero[1], Dr. Rosella Visintin[1]
[1]Department of Experimental Oncology - European Institute of Oncology IRCCS , Milano, Italy

1026 Differentiation of phases in phase change memory materials using 4D STEM

Xue Bai[1], Dr. Janghyun Jo[1], Prof. Dr. Rafal E. Dunin-Borkowski[1]
[1]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, Jülich, Germany

1027 Imaging-based methods to identify prognostic and predictive biomarkers for Hereditary Spastic Paraplegia

Phd Student Gaia Fattorini[1,2], Researcher Valerio Licursi[1], Professor Filippo Maria Santorelli[3], Professor Gabriella Silvestri[4], Professor Carlo Casali[5], Researcher Cinzia Rinaldo[1], PhD Francesca Sardina[1]
[1]Institute of Molecular Biology and Pathology (IBPM), Consiglio Nazionale delle Ricerche (CNR), Rome, Italy, [2]Department of Biology and Biotechnology "Charles Darwin", Sapienza University of Rome, Rome, Italy, [3]IRCCS Stella Maris, Pisa, Italy, [4]UOC Neurologia, Fondazione Policlinico

Universitario 'A. Gemelli' IRCCS, Rome, Italy, [5]Department of Medico-Surgical Sciences and Biotechnologies, University of Rome Sapienza, Latina, Italy

1028 Characterizing Magnetic Properties of Nanoparticle Systems: Insights from Electron Tomography and Micromagnetic Simulations

Cristian Radu[1,2], Andrei Cristian Kuncser[1]
[1]National Institute of Materials Physics, Atomistilor 405A, 077125, , Romania, [2]Faculty of Physics, University of Bucharest, Atomistilor 405, 077125, , Romania

1029 Correlative microscopy of creep cavitation in steels using image processing of SEM, FIB-XeF2 and EBSD

Dr Tomas Martin[1], Dr Siqi He[1], Ms Eirini Gallioupolou[1], Mr Peter Thomas[1], Mr Edward Horton[1], Mr Michael Salvini[1], Dr Nicolo Grilli[1], Professor David Knowles[1], Professor Mahmoud Mostafavi[1], Professor Peter Flewitt[1]
[1]University of Bristol, Bristol, United Kingdom

1030 Insights into Lithium-rich Oxides from Synthesis and Characterization Studies

Rabail Badar Abbasi[1,2,3], Dr Marjan Bele[1], Dr Giuliana Aquilanti[4], Dr Jasper Plaisier[4], Prof. dr Anton Meden[2], Dr Elena Tchernychova[1], Prof. dr Robert Dominko[1,2,3]
[1]Department of Materials Chemistry, National Institute of Chemistry, Ljubljana, Slovenia, [2]Faculty of chemistry and chemical technology, University of Ljubljana, Ljubljana, Slovenia, [3]ALISTORE-European Research Institute, Amiens, France, [4]Elettra-Sincrotrone Trieste S.C.p.A, Trieste, Italy

1031 U-NET Enhanced 4D-STEM/PNBD: Advancing Microscopy Image Reconstruction

Pavlina Sikorova[1], Miroslav Slouf[2], Radim Skoupy[1], Ewa Pavlova[2], Vladislav Krzyzanek[1]
[1]Institute of Scientific Instruments, Czech Academy of Sciences, Brno, Czech Republic, [2]Institute of Macromolecular Chemistry, Czech Academy of Sciences, Prague, Czech Republic

1032 Anomalous effects of strain in selected area diffraction patterns due to boron doping in silicon

Miss Kaviyadharshini Dhamotharan[1], Dr Buddhika Mendis[1]
[1]Durham University , Durham, United Kingdom

1033 Van der Waals heterostructures of nanopatterned 2D materials for novel device geometries

Michael Schlegel[1,2], Jonas Haas[1,2], Kevin Strobel[1,2], Teresa Tang[2], Prof. Dr. Jannik C. Meyer[1,2]
[1]Institute for Applied Physics at University of Tübingen, Tübingen, Germany, [2]Natural and Medical Sciences Institute at the University of Tübingen, Reutlingen, Germany

1034 Fabrication of electron transparent membranes and nanostructures in fluidic devices by NIL and “Flow-Through”-gas-phase deposition

Jeremy Teuber[1], Manuel Müller[1], Rukan Nasri[1], Dr. Irene Fernandez-Cuesta[1]
[1]University of Hamburg, Hamburg, Germany

1035 Electron microscopy studies of Ni/GDC fuel electrode in solid oxide fuel cell

Ardavan Makvandi[1], Yanting Liu[2], Dr. Heike Störmer[1], Dr. André Weber[2], Dr. Martin Juckel[3], Prof. Norbert H. Menzler[3], Prof. Dagmar Gerthsen[1]
[1]Laboratory for Electron Microscopy (LEM), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany, [2]Institute for Applied Materials - Electrochemical Technologies (IAM-ET), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany, [3]Institute of Energy and Climate Research (IEK), IEK-1: Materials Synthesis and Processing, Forschungszentrum Jülich GmbH, Jülich, Germany

1036 Assessing feasibility of detecting photogenerated charge carriers in photocatalysts via transmission electron microscopy: simulation study

Monia Runge Nielsen[1,2], Shima Kadkhodazadeh[1,2], Michael S. Seifner[1,2]
[1]Nanolab - National Centre for Nano Fabrication and Characterization, Technical University of Denmark, Kongens Lyngby, Denmark, [2]NanoPhoton - Center for Nanophotonics, Technical University of Denmark, Kongens Lyngby, Denmark

1037 Unraveling the regulation pathway of photosynthetic AB-GAPDH

Dr Roberto Marotta[1], Dr Alessandra Del Giudice[2], Dr Libero Gurrieri[3], Prof Paolo Trost[4], Prof Simona Fermani[5], Prof Francesca Sparla[6]
[1]Electron Microscopy Facility - Italian Institute of Technology IIT, Genoa, Italy, [2]Department of Chemistry, University of Rome Sapienza, Rome, Italy, [3]Department of Pharmacy and Biotecnology, University of Bologna, Bologna, Italy, [4]Department of Pharmacy and Biotecnology, University of Bologna, Bologna, Italy, [5]Department of Chemistry "G. Ciamician", University of Bologna, Bologna , Italy, [6]Department of Chemistry "G. Ciamician", University of Bologna, Bologna , Italy

1039 Resolving short-range order in Carbon Nitride-based catalysts using EELS

Mr. Teodor Jianu[1], Mr. Horațiu Szalad[1], Dr. Baile Wu[1], Dr. Vladimir Rodatis[2], Prof. Dr. Dr. h.c. Markus Antonietti[1], Dr. habil. Nadezda V Tarakina[1]
[1]Department of Colloid Chemistry, Max Planck Institute of Colloids and Interfaces, Potsdam, Germany, [2]German Research Centre for Geosciences GFZ, Helmholtz Centre Potsdam, Potsdam, Germany

1040 Ex Vivo Metabolic Imaging for Parotid Tumors: Implications for Precise Diagnosis and Customized Treatment

Phd Student Alessia Riente[1,2], Dr Alessio Abeltino[1,2], Dr Cassandra Serantoni[1,2], Dr Michele Maria De Giulio[1,2], Dr Duaa Hatem[1,2], Prof Marco De Spirito[1,2], Dr Mariaconsiglia Santantonio[3], Dr Michela Sollazzo[2], Dr Lela Calò[2], Prof Giulio Cesare Passali[2], Dr Jacopo Galli[2], Prof Giuseppe Maulucci[1,2]
[1] Catholic University of the Sacred Heart, Rome, Italy, [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, [3]Ospedale Pediatrico Bambino Gesù, Rome, Italy

1041 Using XeF2 FIB imaging to contrast and quantify precipitation in metal.

Mr Peter Thomas[1], Dr Mariia Zimina[1], Dr Lawrence Coghlan[1], Mr Aidan Gunn[1], Dr Siqi He[1], Dr Aya Shin[2], Dr Jonathan Pearson[2], Professor Peter Flewitt[1], Dr Tomas Martin[1]
[1]University of Bristol, Bristol, United Kingdom, [2]EDF UK, Gloucester, United Kingdom

1042 Towards Automation of the Transmission Electron Microscope

Kristian Tveitstøl[1], Magnus Nord[1]
[1]Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

1043 In situ SEM of slip localization and its relation to the onset of ductile fracture

Mr Antoine Ollivier, Dr Antonio Pereira, Dr Nicholas Blanchard, Professor Loic Vanel, Dr Döme Tanguy
[1]Universite Claude Bernard Lyon 1, CNRS, Institut Lumière Matière, Villeurbanne, France

1044 In-situ micro-mechanical tests under SEMs

Dr. XiaoMeng Sui[1]
[1]Chemical Research Support, Weizmann Institute of Science, Rehovot, Israel

1045 Electron Diffraction on Biological Samples

Ing. Vendula Hrabalová[1], Ing. Ph.D. Jaromír Bačovský[1], Ing. Radka Martínková[1], Helmut Gnaegi[2], Miloslav Klinger[3]
[1]Delong Instruments, Brno, Czech Republic, [2]Diatome Ltd., Port, Switzerland, [3]Institute of Physics, Czech Academy of Sciences, , Czech Republic

1046 Measurement of atom mobility of gold nanorods via coarse-sampling in quantitative 4D-STEM

Mr Cheng Zhao[1], Ms Zhi Tong Liew[2], Dr Bryan David Esser[3], Dr Alison Funston[2], Prof Joanne Etheridge[3,4]
[1]Department of Material Science and Engineering, Monash University, Clayton, Australia, [2]School of Chemistry, Monash University, Clayton, Australia, [3]Monash Centre for Electron Microscopy, Monash University, Clayton , Australia, [4]School of Physics and Astronomy, Monash University, Clayton , Australia

1047 Cryo-EM as a tool for observing alginate-based hydrogels

Katerina Mrazova[1,2], Anna Havlickova[2], Diana Cernayova[2], Kamila Hrubanova[1], Petr Sedlacek[2], Vladislav Krzyzanek[1]
[1]Institute of Scientific Instruments of the CAS, v. v. i., Brno, Czech Republic, [2]Faculty of Chemistry, Brno University of Technology, Brno, Czech Republic
1048 The effects of B4C network microstructure on the thermoelectrical properties of spark plasma sintered SiC
Dr Salih Cagri Ozer[1], Ceren Korler[1], Prof. Dr. Servet Turan[1,2]
[1]Eskisehir Technical University, Department of Materials Science and Engineering, Eskisehir, Turkey, [2]Ceramic Research Center, Eskisehir, Turkey
1049 Revealing Nanostructural Dynamics: Exploring Inelastic Scattering in Electron Microscopy

Phd Caterina Chiari[1,2], Prof. Marco Beleggia[1], Dr Vincenzo Grillo[2]
[1]University of Modena and Reggio Emilia, Modena, Italy, [2]S3 CNR Nano, Modena, Italy
1050 Fast mass spectrometry imaging for immunohistochemistry
Dr. Mariya Shamraeva[1], Dr. Edith Sandström[1], Kimberly G. Garcia[1], Distinguished Professor Ron M. A. Heeren[1], Dr. Ian G. M. Anthony[1], Dr. Sebastiaan van Nuffel[1]
[1]Maastricht MultiModal Molecular Imaging Institute (M4i), Maastricht, Netherlands
1051 Multiscale 3D organization of human auditory ossicles unveiled by synchrotron small-angle X-ray scattering tensor tomography
Dr Margaux Schmeltz[1], Dr Christian Appel[1], Ginevra Lautizi[2], Irene Rodriguez Fernandez[1], Torne Tänzer[1], Prof. Dr. Med. Lukas Anschuetz[3,4], Dr Meitian Wang[1], Prof. Dr. Marianne Liebi[1,5,6]
[1]Paul Scherrer Institute, Swiss Light Source, Villigen, Switzerland, [2]Department of Physics, University of Trieste, Trieste, Italy, [3]Otorhinolaryngology Dept., Head and Neck Surgery, Inselspital University Hospital, Bern, Switzerland, [4]Hearing Research Laboratory, ARTORG Center, University of Bern, Bern, Switzerland, [5]Department of Physics, Chalmers University of Technology, Gothenburg, Sweden, [6]Institute of Materials, Ecole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland
1052 Carbonic anhydrase immobilization for microscopic investigation of enzyme activity
Dr. Zsófia Bognár[1], Jeannette de Sparra Lundin[2], Sune Christensen[2], Joerg Jinschek[1,3], Jialong Shen[4], Sonja Salmon[4], Stig Helveg[1]
[1]Center for Visualizing Catalytic Processes (VISION), Department of Physics, Technical University of Denmark, Kgs. Lyngby, Denmark, [2]Novonesis A/S, Kgs. Lyngby, Denmark, [3]National Centre for Nano Fabrication and Characterization (DTU Nanolab), Technical University of Denmark, Kgs. Lyngby, Denmark, [4]Textile Biocatalysis Research, Department of Textile Engineering Chemistry & Science, North Carolina State University, Raleigh, USA
1053 Exploring Local Order/Disorder in Relaxor Ferroelectric Materials via TEM and STEM Methods
Beatriz Vargas Carosi[1], PRanjal Nandi[1], Lluís Yedra[1], Sonia Estradé[1], Angélica M. Benitez-Castro[2,3], Juan Muñoz-Saldaña[3], Bernat Mundet[4], Lluís López-Conesa[1], Francesca Peiró[1]

Norponiente 2000, Querétaro, Mexico, [4]Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Campus UAB, Bellaterra, Spain
1054 Structural characterisation of a phage-like bacteriocin from Pseudomonas sp. by cryo-Electron Microscopy
Dr Eilis Bragginton[1], Miles Graham[1,2], Liam Mead[1], Dr Matthew Byrne[1], Dr Karen Davies[1]

[1]Electron Bio-Imaging Centre, Diamond Light Source, Harwell Science and Innovation Campus , Didcot , United Kingdom , [2]Division of Structural Biology, Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom

1055 Structural characterization of partially relaxed hybrid radial (Pb,Sn)Te/WZ-GaAs nanowires as candidates for topological insulator nano-devices

Dr Maciej Wójcik[1], M.sc Sania Dad[1], M.sc Wiktoria Zajkowska-Pietrzak[1], M.sc Piotr Dziawa[1], Prof. Slawomir Kret[1], Prof. Wojciech Pacuski[2], Prof. Janusz Sadowski[3]
[1]Institute of Physics, Polish Academy of Sciences, Warsaw, Poland, [2]Faculty of Physics, University of Warsaw, Warsaw, Poland, [3]Ensemble3 Centre of Excellence, Warsaw, Poland

1056 Histopathologic Alterations of Cerebellum in the VPA-Induced Autism Model of Rats

Dr Sila GUVENIR SEVEN[1], MSc Hakan Sahin[2], Prof. Dr. Gozde Erkanli Senturk[2], Nesibe Uysal[3], Prof. Dr. Hafize Uzun[4], Prof. Dr. Gonul Simsek[1]
[1]Department of Physiology, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Turkey, [2]Department of Histology and Embryology, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Turkey, [3]Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Turkey, [4]Department of Medical Biochemistry, Faculty of Medicine, Atlas University, Istanbul, Turkey

1057 Accessible low-cost, long range, optical autofocus module for open-source multiwell plate and slide scanning microscopy

Miss Sara Habte[1], Mr Miguel Boland[2], Ms Sara Habte[1], Dr Jonathan Lightley[1], Dr Edwin Garcia[1], Professor Christopher Dunsby[1], Dr Edward Cohen[2], Professor Paul French[1]
[1]Physics Department, Imperial College London, London, UK, [2]Mathematics Department, Imperial College London, London, UK, [3]Francis Crick Institute, London, UK

1059 Investigation of self-assembly dynamics of magnetic nanoparticles in liquid phase by transmission electron microscopy

Dr Malika Khelfallah[1], Dr Claire Carvallo[2], Dr Amélie Juhin[2], Dr Govind Ummethala[1], Dr Amir Tavabi[1], Peng-Han Lu[1], Dr Thibaud Denneulin[1], Prof. Dr Rafal Dunin-Borkowski[1]
[1]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich GmbH, Jülich, Germany, [2]Institut de Minéralogie, de Physique des Matériaux et de Cosmochimie, Sorbonne Université, MNHN, CNRS, UMR 7590, Paris, France

1060 3D reconstruction and temporal development analysis of dendritic spines

Mrs. Iva Svecova[1], Stepan Kortus[1]
[1]The Institute of Experimental Medicine CAS, Prague, Czech Republic

1061 Fast large-area EDS characterization of additive manufactured steels

Dylan Bailey[1], Christina Nicole König[1], Dr. Joerg Jinschek[1]
[1]National Centre for Nano Fabrication and Characterization (DTU Nanolab),Technical University of Denmark(DTU), Kgs. Lyngby, Denmark

1062 Novel nanobody-based tools for studying the synaptic vesicle life cycle

Ronja Rehm[1], Nikolaos Mougios[1,2], Karine Queiroz Zetune Villa Real[1,2], Dr. Shama Sograte-Idrissi[1,2], László Albert[1,2], Amir M. Rahimi[1,2], Dr. Manuel Maidorn[1,2], Jannik Hentze[1,2], Dr. Markel Martinez-Carranza[3], Hassan Hosseini[4], Dr. Kim-Ann Saal[1,2], Dr. Nazar Oleksiievets[5], Dr. Matthias Prigge[4], Dr. Roman Tsukanov[5], Dr. Pål Stenmark[3], Dr. Silvio Rizzoli[1,2], Dr. Felipe Opazo[1,2], Dr. Eugenio Fornasiero[1]
[1]University Medical Center, Neuro- and Sensory physiology, Göttingen, Germany, [2]University Medical Center, Center for Biostructural Imaging of Neurodegeneration (BIN), Göttingen, Germany, [3]Stockholm University, Department of Biochemistry and Biophysics, Stockholm, Sweden, [4]Research Group Neuromodulatory Networks, Leibniz Institute for Neurobiology, Magdeburg, Germany, [5]Georg August University, III. Institute of Physics - Biophysics, Göttingen, Germany

1063 Correlative TOF-SIMS/SEM for subcellular molecular profiling of snow microalgae

Claire Seydoux[1], Jade Ezzedine[2], Eric Maréchal[2], Jean-Paul Barnes[3], Pierre-Henri Jouneau[1]
[1]Laboratoire Exploration et Modélisation des Matériaux, Grenoble, France, [2]Laboratoire de Physiologie Cellulaire et végétale, Grenoble, France, [3]CEA-Leti, Grenoble, France

1064 Correlative TOF-SIMS/SEM for subcellular molecular profiling of snow microalgae

Claire Seydoux[1], Ezzedine Jade[2], Eric Maréchal[2], Jean-Paul Barnes[3], Pierre-Henri Jouneau[1]
[1]Laboratoire Modélisation et Exploration des Matériaux, Grenoble, France, [2]Laboratoire de Physiologie Cellulaire et Végétale, Grenoble, France, [3]CEA-Leti, Grenoble, France

1065 Innovative Microfluidic chip for Raman spectroscopy and advanced electron microscopy techniques

Ing. Tomas Laznicka[1], Jan Jezek[1], Kamila Hrubanova[1], Vladislav Krzyzanek[1]
[1]Institute of Scientific Instruments, The Czech Academy of Sciences, v.v.i., Brno, Czech Republic

1066 Electrons phase reconstruction using Kramers-Kronig relations

Dr. Yang Yin[1], Dr. Wenhao He[1], Prof. Changlin Zheng[1]
[1]Department of Physics,Fudan University, Shanghai, China

1067 Compartmentalization of synaptic ER studied by correlative FLIP and FIB-SEM

Dr. Helena Vihinen[1], Dr. Leena-Stiina Kontturi[2], Asst. Prof. Juha Saarikangas[2], Dr. Eija Jokitalo[1]
[1]Electron Microscopy Unit, Helsinki Institute of Life Science, Institute of Biotechnology, University of Helsinki, Helsinki, Finland, [2]Helsinki Institute of Life Science and Faculty of Biological and Environmental Sciences, University of Helsinki, , Finland

1068 Investigation of the Presence of Telocyte-like Cells in Human Patellar Fat Pad Tissue

Professor Doctor Gamze Tanriverdi[1], MD. PhD Merjem Purelku[1], Ph.D Zehra Sezer[1], Specialist Doctor Duygu Neccar[1], M.sC. Naziya Bagirova[1], Research Assistant Yonca Aras[1], Associate Professor Ersin Erçin[2], Specialist Doctor Alican Koluman[2], Professor Doctor Gozde Erkanli Senturk[1], Associate Professor Bulent Tanriverdi[2]
[1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Histology and Embryology Department , Istanbul , Turkey , [2]Department of Orthopedics and Traumatology, Istanbul Bakirkoy Dr. Sadi Konuk Education and Research Hospital, University of Health Sciences, Istanbul, Turkey

1069 WDS-supported Bayesian Peak Deconvolution for optimized Standardless EDS-Quantification

Jörg Nissen[1], Frank Eggert[2], Dirk Berger[1], Ulrich Gernert[1]
[1]Technische Universität Berlin, Center for Electron Microscopy (ZELMI) , Berlin, Germany, [2]Microanalyst.net, Berlin, Germany

1070 Visualizing atomic structure of novel three-dimensional covalent organic frameworks by 3DED and high-resolution (S)TEM

Jia Lyu[1], Yaozu Liu[2], Professor Qianrong Fang[2], Professor Xiaodong Zou[1], Researcher Hongyi Xu[1], Professor Daliang Zhang[3]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden, [2]State Key Laboratory of Inorganic Synthesis and Preparative Chemistry, Jilin University, Changchun, P. R. China, [3]Multi-Scale Porous Materials Center, Institute of Advanced Interdisciplinary Studies & School of Chemistry and Chemical Engineering, Chongqing University, Chongqing, P. R. China

1071 Investigation of GaAs-based nanowire heterostructures using tomography based on STEM-HAADF tilt-series[1]

Richard Zell[1], Sebastian Sturm[1], Hyowon W. Jeong[2], Prof. Gregor Koblmüller[2], Prof. Knut Müller-Caspary[1]
[1]Ludwig-Maximilians-Universität, Munich, Germany, [2]Technical University of Munich, Munich, Germany

1072 Single-camera multi-color emission anisotropy optical splitter

Mrs Greeshma Pradeep S[1], Mrs Charitra Sree Senthil Kumar[1], Dr Abhishek Kumar[2], Dr Thomas S van Zanten[1,3]

[1]Cell Biology Group, National Center for Biological Sciences, Tata Institute of Fundamental Research, Bellary Road, Bangalore, India, [2]Marine Biological Laboratory, Woods Hole, United States, [3]Instituto de Nanociencia y Materiales de Aragon, Zaragoza, Spain

1073 Influence of damage dose on the defect formation in tungsten

Dipl.-Ing. Ute Jäntsch[1], Dr. Michael Klimenkov[1], Dr. Michael Rieth[1], Dr. Thomas Schwarz-Selinger[2], Dr. Mikhail Zibrov[2]
[1]Institute of Applied Materials, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany, [2]Max-Planck-Institut für Plasmaphysik (IPP), Garching, Germany

1074 Label-free biological composition predictions in EM images

Msc Stijn Karaçoban[1], PhD Ryan Lane[1], MSc Daniel Spengler[2], BSc Anouk Wolters[3], Associate Professor Carlas, S. Smith[2], Associate Professor Jacob, P. Hoogenboom[1]
[1]Imaging Physics, Delft University of Technology, Delft, The Netherlands, [2]Delft Center for Systems and Control, Delft University of Technology, Delft, The Netherlands, [3]Cell Biology, University Medical Center Groningen, Groningen, The Netherlands

1075 Measurement of EELS standards and application on oxidation state determination of a MeOH catalyst

Dr. Daniela Ramermann[1], Dr. Elisabeth H. Wolf[1], Dr. Michael Poschmann[1], Dr. Christoph Göbel[1], Dr. Lukas Pielsticker[1], Dr. Holger Ruland[1], Dr. Walid Hetaba[1]
[1]Max Planck Institute for Chemical Energy Conversion, Department of Heterogeneous Reactions, Mülheim an der Ruhr, Germany

1076 Numerical Analysis of Temperature Calibration using Plasmon Energy Expansion Thermometry

Lucas Pedersen[1], Yi-Chieh Yang[2], Mads Sørensen[3], Joerg Jinschek[4]
[1]Department of Applied Mathematics and Computer Science, Technical University of Denmark (DTU), Kgs. Lyngby, Denmark, Kgs. Lyngby, Denmark, [2]National Center for Nano Fabrication and Characterization, Technical University of Denmark (DTU), Kgs. Lyngby, Denmark, , , [3]Department of Applied Mathematics and Computer Science, Technical University of Denmark (DTU), Kgs. Lyngby, Denmark, , , [4]National Center for Nano Fabrication and Characterization, Technical University of Denmark (DTU), Kgs. Lyngby, Denmark, ,

1077 Corrosion of Alloys Suitable for Very High Temperature Systems (VHTRs) Exposed to High Temperature Helium

Dr Lawrence Coghlan[1], Dr Mariia Zimina[1], Dr Robert Burrows[3], Dr Aya Shin[2], Dr Tomas Martin[1]
[1]University of Bristol, Bristol, United Kingdom, [2]EDF Energy, Gloucester, United Kingdom, [3]National Nuclear Laboratory, Bristol, United Kingdom

1078 Optimizing Soft X-ray Spectroscopy for Silicon Anode Lithium Mapping

M. Sc. Svenja Kalthoff[1]
[1]Fraunhofer ISE, Freiburg im Breisgau, Germany

1079 Operando TEM Studies of Re@Cu2O-SnO2 catalysts during CO2 reduction reaction with optimized liquid flow configuration

Ms Cecilia Irene Gho[1,2], Dr Katarzyna Bejtka[1,2], Dr Marco Fontana[1,2], Dr Maria José López Tendero[3], Dr. Alberto Lopera López[3], Dr Roger Miro Serra[4], Dr Miriam Díaz de los Bernardos[4], prof Simelys Hernández[2], Dr Hilmar Guzmán[2], Dr Stefan Merkens[5], prof Andrey Chuvilin[5,6], prof Candido Fabrizio Pirri[1,2], Dr Angelica Chiodoni[1]
[1] Center for Sustainable Future Technologies @Polito, Istituto Italiano di Tecnologia, Via Livorno 60, 10144 , Torino, Itlay, [2]Department of Applied Science and Technology, Politecnico di Torino, Corso Duca degli Abruzzi 24, 10129 , Torino, Italy, [3]Laurentia Technologies Avda. Benjamin Franklin, 12 (CEEI) Parque Tecnológico/ 46980, Paterna (Valencia), Spain, [4]Centro Tecnológico de Catalunya, Eurecat, Campus Sescelades de la URV. [5]Electron Microscopy Laboratory, CIC nanoGUNE BRTA, Tolosa Hiribidea 76, Donostia, San Sebastian, Spain, [6]Ikerbasque, Basque Foundation for Science, 48013 , Bilbao, Spain

1080 CAR T cell dynamics in a 3D collagen matrix: migration and interactions with cancer cells

Nicoline Dorothea Daugaard[1], Mike Bogetofte Barnkob[2], Zelvera Ismetova Usheva[2], Torben Barington[2], Jonathan R. Brewer[1]
[1]Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark, [2]Centre for Cellular Immunotherapy of Haematological Cancer Odense (CITCO), Department of Clinical Immunology, Odense University Hospital, University of Southern Denmark, Odense, Denmark

1081 Analysis of the local chain orientation in conjugated polymer films

Mr Timothy Lambden[1], Dr Joonatan Laulainen[1], Dr Maximilian Moser[2], Dr Christina Kousseff[2], Professor Iain McCulloch[2,3], Dr Scott Keene[4,5], Professor Paul Midgley[1]
[1]Department of Materials Sciences and Metallurgy, University of Cambridge,, Cambridge, United Kingdom, [2]2Department of Chemistry, Chemistry Research Laboratory, University of Oxford, Oxford, United Kingdom, [3]Department of Electrical and Computer Engineering, Engineering Quadrangle, 41 Olden Street, Princeton, USA, [4]4Electrical Engineering Division, Department of Engineering, University of Cambridge, Cambridge, UK, [5]5Cavendish Laboratory, University of Cambridge, , Cambridge, UK

1082 Resolving single-electron and multi-electron distribution functions with event-based electron detectors

Alexander Schröder[1], Andreas Wendeln[1], Prof. Sascha Schäfer[1]
[1]University Regensburg, Regensburg, Germany

1083 Structured illumination near-field electron ptychography

Penghan Lu[1], Frederick Allars[2], Shengbo You[3], Thomas Schachinger[4], Rafal E. Dunin-Borkowski[1], Andrew M. Maiden[2,3]
[1]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, Jülich, Germany, [2]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, UK, [3]Department of Electronic and Electrical Engineering, University of Sheffield, Sheffield, UK, [4]University Service Centre for Transmission Electron Microscopy, TU Wien, Wien, Austria

1084 Geometric phase analysis-based characterization of skyrmion lattice equilibria

M.Sc Vinko Sršan[1,2], Asst. Prof. Matej Komelj[2], Prof. Sašo Šturm[1,2,3]
[1]Jožef Stefan International Postgraduate School, Ljubljana, Slovenia, [2]Department for Nanostructured Materials, Jožef Stefan Institute, Ljubljana, Slovenia, [3]Department of Geology, Faculty of Natural Sciences and Engineering, University of Ljubljana, Ljubljana, Slovenia

1085 Electron microscopy characterization of grain boundaries in Nb1-xTixFeSb based half-Heusler thermoelectric materials

Dominique Mattlat[1], Dr. Ruben Bueno Villoro[1], Dr. Chanwon Jung[1], Raana Hatami Naderloo[2], Dr. Ran He[2], Prof. Dr. Kornelius Nielsch[2], Duncan Zavanelli[3], Prof. Dr. G. Jeffrey Snyder[3], Dr. Siyuan Zhang[1], Prof. Dr. Christina Scheu[1]
[1]Max-Planck-Institute for Iron Research, Düsseldorf, Germany, [2]Leibniz Institute for Solid State and Materials Research, Dresden, Germany, [3]Northwestern University, Chicago, United States of America

1086 Interference based optical instrument for high-throughput characterization of nanoparticles in complex biofluids

M.Sc.(Eng.) Carl Emil Schøier Kovsted[1], M.Sc. Yingchao Li[1], M.Sc.(Eng.) Lasse Pærgård Kristiansen[1], Ph.D. Jeppe Revall Frisvad[2], Ph.D. Jaco Botha[1], Ph.D. Emil Boye Kromann[1]
[1]Department of Health Technology, Technical University of Denmark, Kgs. Lyngby, Denmark, [2]Department of Applied Mathematics and Computer Science, Technical University of Denmark, Kgs. Lyngby, Denmark

1087 Observing the in-situ formation of the lead-free piezoceramic potassium sodium niobate (KNN) with SAED
Dr Mark Rambaran[1], Dr Daniel Jacobsson[1,2], Dr Sebastian Lehmann[3], Prof. Kimberly Dick[1]
[1]Centre of Analysis and Synthesis and NanoLund, Lund University, Lund, Sweden, [2]National Centre for High Resolution Electron Microscopy , Lund University, Lund, Sweden, [3]Division of Solid State Physics and NanoLund, Lund University, Lund, Sweden
1088 Quarantotto: a 48-segment STEM detector for enhanced STEM performance and new applications
Dr Stefano Vespucci[1], Dr Eric G.T. Bosch[1], Dr Ivan Lazić[1], Bert de Vries[1], Dr Ricardo Egoavil[1], Dr Bert Freitag[1], Dr Tim Grieb[2], Dr Florian F. Krause[2], Dr Martin Eickhoff[2], Prof Andreas Rosenauer[2]
[1]Thermo Fisher Scientific, Eindhoven, The Netherlands, [2]Institute of Solid-State Physics, University of Bremen, Bremen, Germany
1089 Correlative Microscopy Analysis of Jack Hills Zircons by Photonic Atom Probe
Dr. Florant Exertier[1], Dr. Jonathan Houard[1], Dr. Martin Bizzarro[2], Dr. Rick Verberne[2], Dr. Lorenzo Rigutti[1]
[1]Univ Rouen Normandie, INSA Rouen Normandie, CNRS, Normandie Univ, GPM UMR 6634, Rouen, France, [2]Center for Star and Planet Formation, GLOBE Institute, University of Copenhagen, Copenhagen, Denmark
1090 Fabrication and high-resolution transmission electron microscopy characterization of nanopores in silicon nitride and 2D materials
Teresa Tang[1], Marco Kögel[1], Michael Mierzejewski[1], Michael Schlegel[1,2], Peter D. Jones[1], Jannik C. Meyer[1,2]
[1]NMI Natural and Medical Sciences Institute at the University of Tübingen, Reutlingen, Germany, [2]Institute of Applied Physics, University of Tübingen, Tübingen, Germany
1091 Microstructure of light-emitting phosphor of (Sr, Ca)AlSiN3:Eu2+
Hajime Matsumoto[1]
[1]Mitsubishi Chemical Corp., Yokohama, Japan, [2]National Institute for Materials Science, Tsukuba, Japan
1092 Molecular dynamics simulation of the Brownian motion of biomolecules in liquid phase electron microscopy
Mr Xiaopeng Wu[1], Dr Peng Wang[1]
[1]Department of Physics, University of Warwick, Coventry, United Kingdom
1093 Multifunctional hybrid nanocomposite films: linking inorganic nanoparticles using α-synuclein as molecular linker
Prof Patrizia Canton[1], Prof Adolfo Speghini[2], Dr Emil Milan[2], Dr R Tira[2], Dr. M. D'Onofrio[2], Dr M Assfalg[2]
[1]Department of Molecular Sciences and Nanosystems, Ca' Foscari University of Venice , Venezia, Italy, [2]Department of Biotechnology, University of Verona, Verona, Italy
1094 Quantitative EMCD analysis of Fe thin films on MgOx substrates
Mr. Sharath Kumar Manjeshwar Sathyanath[1], Dr Anna L. Ravensburg[2], Professor Vassilios Kapaklis[2], Professor Björgvin Hjörvarsson[2], Professor Klaus Leifer[1]
[1]Department of Materials Science and Engineering, Uppsala University, Uppsala, Sweden, [2]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden
1095 Laboratory Soft X-ray Microscopy for Biomedical Applications
Aurélie Dehlinger[1,2], Dr. Christian Seim[1,2], Valentina Alberini[1,2], Dr. Holger Stiel[2,3], Dr. Antje Ludwig[4,5,6], Sarah Jung[1,2], Daniel Groetzsch[1,2], Vladimir Usatikov[1,2], Dr. Johannes Tuemmler[3], Prof. Dr. Birgit Kanngießer[1,2]

[1]Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany, [2]Berlin Laboratory for innovative X-ray technologies (BLiX), Berlin, Germany, [3]Max-Born-Institut (MBI) im Forschungsverbund Berlin e.V., Berlin, Germany, [4]Department of Cardiology, Angiology and Intensive Care Medicine, Deutsches Herzzentrum der Charité, Berlin, Germany, [5]Department of Cardiology, Angiology and Intensive Care Medicine, Charité - Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, [6]DZHK (German Centre for Cardiovascular Research), Partner Site Berlin, Berlin, Germany

1096 Nanowire field emitters fabricated using focused electron, gallium and helium ion beam methods

Ewelina Gacka[1], Krzysztof Kwoka[1], Tomasz Piasecki[1], Gregor Hlawacek[2], Bartosz Pruchnik[1], Ivo W. Rangelow[3], Andrzej Sierakowski[4], Paweł Janus[4], René Hübner[2], Teodor Gotszalk[1]
[1]Department of Nanometrology, Wrocław University of Science and Technology, 50-372, Wrocław, Poland, [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328, Dresden, Germany, [3]Technische Universität Ilmenau, 98693, Ilmenau, Germany, [4]The Łukasiewicz Research Network - Institute of Microelectronics and Photonics, , Poland

1097 Investigation of Lateral and Vertical Heterostructures of MoS2/WS2

Jürgen Belz[1], Dr. Oliver Maßmeyer[1], Samane Ojaghi Dogahe[1], Dr. Andreas Beyer[1], Henrik Myja[2], Tillmar Kümmell[2], Bacher Gerd[2], Michael Heuken[3], Annika Grundmann[4], Holger Kalisch[4], Andrei Vescan[4], Kerstin Volz[1]
[1]Department of Physics & Structure & Technology Research Laboratory, Marburg, Germany, [2]Werkstoffe der Elektrotechnik & CENIDE, University of Duisburg-Essen, Duisburg-Essen, Germany, [3]AIXTRON SE, Herzogenrath, Germany, [4]Compound Semiconductor Technology, RWTH Aachen University, Aachen, Germany

1098 In-Situ microscopy study on self-healing process of vitrimers

Tobias Krekeler[1], Siraphat Weerathaworn[2], Matthias Hemmleb[3], Volker Abetz[2], Martin Ritter[1]
[1]Hamburg University of Technology, Hamburg, Germany, [2]University of Hamburg, Hamburg, Germany, [3]point electronic GmbH, Halle (Saale), Germany

1099 Deep learning-based single cell volume segmentation for soft X-ray microscopy data

Valentina Alberini[1,2], Aurélie Dehlinger[1,2], Dr. Christian Seim[1,2], Dr. Holger Stiel[2,3], Dr. Antje Ludwig[4], Prof. Dr. Birgit Kanngießer[1,2]
[1]Technische Universität Berlin, Berlin, Germany, [2]Berlin Laboratory for innovative X-ray technologies (BLiX), Berlin, Germany, [3]Max-Born-Institute (MBI), Berlin, Germany, [4]Charité Universitätsmedizin Berlin, Berlin, Germany

1100 Insights into the formation of polycrystalline seed layers for the solution growth of semiconductor nanorods

Sarka Kucerova[1,2], Dr. Jozef Veselý[2], Dr. Michal Mazur[3], Jan Macháček[1], Matěj Berešík[1], Dr. Nikola Bašinová[1], Dr. Roman Yatskiv[1], Prof. Seungbum Hong[4], Dr. Jan Grym[1], Seongwoo Cho[5]
[1]Institute of Photonics and Electronics, CAS, Chaberská 57, 18251, Praha 8, Czech Republic, [2]Faculty of Mathematics and Physics, Charles University, Ke Karlovu 3, 121 16, Praha 2, Czech Republic, [3]Faculty of Science, Charles University, Hlavova 8, 128 43, Praha 2, Czech Republic, [4]Korea Advanced Institute of Science and Technology, 291 Daehak-ro, Yuseong-gu Daejeon 34141, Republic of Korea

1101 SoftGrids: towards disease modelling in CryoEM

Abstract Submission Asena Oelschläger[1], Prof. Dr. Stefan Raunser[1], Dr. Sebastian Tacke[1]
[1]Max-Planck-Institut für molekulare Physiologie, Dortmund,

1102 Room temperature viscoplastic response of amorphous olivine films revealed by ex/in-situ TEM nanomechanical testing

Dr Armand Béché[1]
[1]IMAP/LACaMi - UCLouvain, Louvain-La-Neuve, Belgium

1103 Low-dose 4D-STEM cryo-tomography of biological samples
Dr. Shahar Seifer[1], Shai Kiriati[1], Dr. Peter Kirchweger[1], Prof. Michael Elbaum[1]
[1]Weizmann Institute of Science, Rehovot, Israel
1104 Ultra-low-cost, high-dynamic-range, additively manufactured CMOS spectrometers with UV, visible, and NIR sensing functionality
Mr. Hironori Kondo[1,2]
[1]John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, USA, [2]Department of Chemistry and Chemical Biology, Cambridge, USA
1105 Correlative microscopy for the discovery of novel nano-grains in spintronic materials.
Dr Adam Kerrigan[1], Dr Irene Azaceta[2], Dr Ercin Duran[3], Dr Stuart Cavill[2], Dr Alex Eggeman[3], Prof Vlado Lazarov[1,2]
[1]The York-JEOL Nanocentre, University of York, York, United Kingdom, [2]School of Physics, Engineering and Technology, University of York , York, United Kingdom, [3]Department of Materials, University of Manchester, Manchester, United Kingdom
1106 Hyperspectral Imaging with 'Spectromics': Label-free Chemical Mapping in the NIR-SWIR for Tissue Diagnostics
Mr Hiroki Cook Cook[1,2], Dr Anna Crisford[1,2,3], Dr Konstantinos Bourdakos[1,2], Mr Douglas Dunlop[4], Professor Richard Oreffo[2,3], Professor Sumeet Mahajan[1,2]
[1]School of Chemistry, University of Southampton, Southampton, United Kingdom, [2]Institute for Life Sciences, University of Southampton, Southampton, United Kingdom, [3]Human Development and Health, University of Southampton, Southampton, United Kingdom, [4]University Hospital NHS Foundation Trust, Southampton, United Kingdom
1107 Simultaneous nanoscale mapping of strain and electric field in semiconductor heterostructures using 4D-STEM
Yucheng Zou[1], Dr. Lei Jin[1], Peng-Han Lu[1], Prof. Dr Rafal Dunin-Borkowski[1]
[1]Research Center Jülich, Jülich, Germany
1108 Novel In-situ TKD Nano-tensile Testing: Insights into Nanoscale Crystal Plasticity and Grain Boundary Mechanics
Dr. Tijmen Vermeij[1], Dr. Amit Sharma[1], Dr. Xavier Maeder[1], Prof. Johann Michler[1]
[1]Laboratory for Mechanics of Materials and Nanostructures, Swiss Federal Laboratories for Materials Science and Technology (EMPA), Thun, Switzerland
1109 Physical and chemical parameters determining the formation of gold sp-metal (Al, Ga, In, Pb) nanoalloys
Prof Patrizia Canton[1], Prof Vincenzo Amendola[2], Dr Vito Coviello[2], Dr Daniel Forrer[3]
[1]Department of Molecular Sciences and Nanosystems, University Ca' Foscari of Venice, Venezia, Italy, [2]Department of Chemical Sciences, University of Padova, Padova, Italy, [3]CNR– ICMATE, Padova, Italy
1110 Sample holder design for TEM in-situ straining experiments on 2D materials
Carmen Rubach[1], Dr. Xin Zhou[1], Tobias Dierke[2], Robert Kammel[1], Michael Sommerschuh[1], Prof. Janina Maultzsch[2], Prof. Erdmann Spiecker[1]
[1]Institute of Micro- and Nanostructure Research (IMN) & Center for Nanoanalysis and Electron Microscopy (CENEM), Friedrich-Alexander-University Erlangen-Nürnberg, 91058 Erlangen, Germany, [2]Institute of Condensed Matter Physics, Friedrich-Alexander-University Erlangen-Nürnberg, 91058 Erlangen, Germany
1111 Synthetic Bispecific RBD Antibody Effectively Neutralizes SRAS-CoV-2
Uijin Kim[1], Dong-Gun Kim[2], Inho Park[3], Youngki Yoo[1], Bumhan Ryu[4], Ga-Yeon Yoon[1], Kitaek Nam[3], Jeonsoo Shin[3], Hak-Sung Kim[1], Hyun-Soo Cho[1]

[1]Department of Systems Biology, Yonsei University, Seoul 03722, Korea, [2]Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, [3]Department of Microbiology, Yonsei University College of Medicine, Seoul, Korea, [4]Institute for Basic Science (IBS), Daejeon, Korea

1112 Structure and stability of core-shell AuTiOx nanoparticles for CO oxidation

Stefan Kei Akazawa[1], Rikke Egeberg Tankard[2], Filippo Romeggio[2], Jakob Kibsgaard[2], Ib Chorkendorff[2], Stig Helveg[1], Christian Danvad Damsgaard[1,2,3]
[1]Center for Visualizing Catalytic Processes (VISION), Department of Physics, Technical University of Denmark, Kgs. Lyngby, Denmark, [2]Surface Physics and Catalysis, Department of Physics, Kgs. Lyngby, Denmark, [3]National Center for Nano Fabrication and Characterization, Kgs. Lyngby, Denmark

1113 MEMS Monochromator

Martijn Adriaans[1], Dr. Jacob Hoogenboom[1], Dr. Ali Mohammadi-Gheidari[1]
[1]Delft University of Technology, Delft, The Netherlands

1114 Structural characterization of single wall carbon nanotubes via AI assisted transmission electron microscopy

Dr. Antonin Louiset[1], Dr Daniel FÖRSTER[2], Ms. Eira MEDINA[3], Mr. Saïd TAHIR[3], Dr. Vincent JOURDAIN[3], Dr. Christophe BICHARA[4], Dr. Hanako OKUNO[1]
[1]IRIG-MEM, CEA, Université Grenoble Alpes, Grenoble, France, [2]Laboratoire d'Etude des Microstructures, ONERA-CNRS, Université Paris-Saclay, Châtillon, France, [3]Laboratoire Charles Coulomb, CNRS, Université de Montpellier, Montpellier, France, [4]CINaM, CNRS, Université Aix-Marseille, Marseille, France

1115 Investigating nanoparticle interactions with the human blood-brain barrier in vitro

Hakan Sahin[1], Oguz Yucel[2], Dr. Paul Holloway[3], Eren Yildirim[2], Dr. Serkan Emik[2], Dr. Gulten Gurdag[2], Dr. Gamze Tanriverdi[1], Dr. Gozde Erkanli Senturk[1]
[1]Department of Histology and Embryology, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Turkey, [2]Department of Chemical Engineering, Faculty of Engineering, Istanbul University-Cerrahpasa, Istanbul, Turkey, [3]Radcliffe Department of Medicine, University of Oxford, Oxford, UK

1116 Effects of swimming training on orexin receptor 2 distribution in brain damage of rats

Professor Dilek Akakın[1], Assoc. Prof. Merve Acikel Elmas[2], Phd Student Ayca Karagoz Koroglu[1], Assoc. Prof. Ozlem Bingol Ozakpinar[3], Prof. Filiz Onat[4], Professor Feriha Ercan[1]
[1]1, Istanbul, Turkiye, [2]2, Istanbul, Turkiye, [3]3, Istanbul, Turkiye, [4]4, Istanbul, Turkiye

1117 Towards Single-Pattern Absolute High angular Resolution EBSD without using Simulated Patterns as Reference

Dr. Tijmen Vermeij[1,2], Lloyd Dodsworth[1], Dr. Aimo Winkelmann[3], Dr. René De Kloe[4], Dr. Johan Hoefnagels[1]
[1]Mechanical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands, [2]Laboratory for Mechanics of Materials and Nanostructures, Swiss Federal Laboratories for Materials Science and Technology (EMPA), Thun, Switzerland, [3]AGH University of Science and Technology, Krakow, Poland, [4]EDAX, Tilburg, Netherlands

1118 Microscopy to discern cells behaviour on different nano/microstructured calcium phosphates ceramics

Dr. Eva Filová[1], Dr. Carolina Oliver-Urrutia[2], Dr. Věra Hedvičáková[1], Dr. Veronika Hefka Blahnová[1], Ms. Eva Šebová[1], Ms. Radmila Žižková[1], Assoc. Prof. Karel Dvořák[2], Assoc. Prof. Ladislav Čelko[2], Dr. Edgar Montufar[2]
[1]Institute of Experimental Medicine, Czech Academy of Sciences, Prague, Czech Republic, [2]Central European Institute of Technology, Brno University of Technology, Prague, Czech Republic

1119 Towards direct imaging of defects in carbon nanotubes with 4DSTEM

Dr. Antonin Louiset[1], Dr. Daniel FÖRSTER[2], Dr. Jean-Luc ROUVIERE[1], Dr. Vincent JOURDAIN[3], Dr. Christophe BICHARA[4], Dr. Hanako OKUNO[1]
[1]IRIG-MEM, CEA, Université Grenoble Alpes, Grenoble, France, [2]Laboratoire d'Etude des Microstructures, ONERA-CNRS, Université Paris-Saclay, Châtillon, France, [3]Laboratoire Charles Coulomb, CNRS, Université de Montpellier, Montpellier, France, [4]CINaM, CNRS, Université Aix-Marseille, Marseille, France
1120 Multimodal imaging accelerates the analysis of composition in bone implant sites
Joshua Lea[1], Pedro Machado[1], Zhidao Xia[2], Dr Louise Hughes[1]
[1]Oxford Instruments NanoAnalysis, High Wycombe, United Kingdom, [2]Centre for Nanohealth, Institute of Life Science, Swansea University Medical School, Swansea , United Kingdom
1121 Investigation of composition and origin of the intermediate layers at the Ga2O3/AlN and Ga2O3/Al2O3 interfaces
Dr. Marco Schowalter[1], S. Raghuvansy[1], Dr. A. Karg[1], Dr. P. Vogt[1,2], Dr. D. Schlom[3], Dr. D. Jena[3], Dr M. Eickhoff[1,2], Dr. A. Rosenauer[1,2]
[1]Institut für Festkörperphysik, Universität Bremen, Bremen, Germany, [2]MAPEX center for material science and processes, Universität Bremen, Bremen, Germany, [3]Department of Material Science and Engineering, Cornell University, Ithaca, USA
1122 Cryo-electron microscopy for the study of sensitive energy materials
Dr. Zdravko Kochovski[1], Dr. Yaolin Xu[1], Prof. Dr. Yan Lu[1]
[1]Department of Electrochemical Energy Storage, Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany
1123 Automated Identification of Slip System and Twinning Activity Fields from Digital Image Correlation Data
Dr. Tijmen Vermeij[1,2], Dr. Ron Peerlings[1], Prof. Marc Geers[1], Dr. Johan Hoefnagels[1]
[1]Mechanical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands, [2]Laboratory for Mechanics of Materials and Nanostructures, Swiss Federal Laboratories for Materials Science and Technology (EMPA), Thun, Switzerland
1124 SEM Automated Quantitative Mineralogy Method-development with Mineralogic: 200-nm-resolution Quantitative Assessment and Mineral-specific element mapping
Phd Nynke Keulen[1], MSc Sebastian N. Malkki[1], PhD Rikke Weibel[1], PhD Adam Garde[1]
[1]GEUS: Geological Survey of Denmark and Greenland, Copenhagen,
1125 Depositing biological segmentation datasets FAIRly
Dr Elaine Ho[1], Dr Dimitris Ladakis[1], Dr Michele C. Darrow[1]
[1]Artificial Intelligence and Informatics, The Rosalind Franklin Institute, Harwell, United Kingdom
1126 Mapping Li in thin-films and heterostructures by EELS and ptychography: case of Li7La3Zr2O12 and LiCoO3
Dr Adam Kerrigan[2], Dr Connor Murril[2], Dr Demie Kepaptsoglou[1,3], Dr Chris Allen[4], Dr Mohsen Danaie[4], Dr Frederick Allars[4], Prof Vlado Lazarov[1,2]
[1]School of Physics, Engineering and Technology, University of York, York, UK, [2]The York-JEOL Nanocentre, University of York, York, UK, [3]SuperSTEM Laboratory, SciTech Daresbury, Daresbury, UK, [4]Electron Physical Science Imaging Centre, Diamond Light Source Ltd., Oxford, UK
1127 Spectrally resolved brightfield widefield microscopy by an ordinary digital camera

Prof. Dalibor Štys[1], Dr. Renata Stysova Rychtarikova[1], Dr. Kirill Lonhus[1]
[1]Visible Truth, Institute of Complex Systems FFPW, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses, University of South Bohemia in České Budějovice, Nové Hrady, Czechia
1128 Nanoparticle Self Diffraction in the TEM: A proposal

Prof. Stefan Nimmrichter[1], Prof. Dennis Rätzel[2,3], Prof. Peter Schattschneider[4,5], Prof. Philipp Haslinger[4,6]
[1]Naturwissenschaftlich-Technische Fakultät, Universität Siegen,, Siegen, Germany , [2]Institut für Physik, Humboldt-Universität zu Berlin, Berlin, Germany, [3]ZARM, University of Bremen, Bremen, Germany, [4]USTEM, TU Wien, Vienna, Austria, [5]Institute of Solid State Physics, TU Wien, Vienna, Austria, [6]Vienna Center for Quantum Science and Technology, Atominstitut, TU Wien, Vienna, Austria

1129 Tungsten nanoparticles generated in an atmospheric pressure plasma jet

Dr. Martin Müller[1], Maren Dworschak[2], Prof. Jan Benedikt[2], Prof. Lorenz Kienle[1]
[1]Faculty of Engineering, Kiel University, Kiel, Germany, [2]Faculty of Mathematics and Natural Sciences, Kiel University, Kiel, Germany

1130 Development of multiciliated cells in the respiratory and esophageal epithelium of the chicken embryo

Dr. Sebastian Reinke[1], Dr. Alexander Reinke[1], Dr. Marcus Frank[1,2]
[1]Medical Biology and Electron Microscopy Centre, University Medicine Rostock, 18055 Rostock, Germany, [2]Department Life Light & Matter, University of Rostock, 18051 Rostock, Germany

1131 In-situ synthesis of thin kesterite films using high voltage TEM

Professor Klaus Leifer[1], Mr Sharath Sathyanath[1], Professor Y Gong[2], Dr Alex J. Arguijo[2], Prof Edgardo Saucedo[2], Professor S Araj[3], Professor Shun Muto[3]
[1]Uppsala University, Uppsala, Sweden, [2]Univ. Politèc. de Catalunya, Barcelona, Spain, [3]Nagoya University, Nagoya, Japan

1132 Morphology evolution and phase transition of $Co(OH)_2$ and Co_3O_4 investigated with STEM-tomography and in-situ XRD

Olivia Kaya Gerds[1,2,3], Lars Fahl Lundegaard[3], Hanne Falsig[3], Christian Danvand Damsgaard[1,2,4], Lars Pilsgaard Hansen[3]
[1]Center for Visualizing Catalytic Processes (VISION), Department of Physics, Technical University of Denmark, Kgs. Lyngby, Denmark, [2]Surface Physics and Catalysis, Department of Physics, Technical University of Denmark, Kgs. Lyngby, Denmark, [3]Topsoe A/S, Kgs. Lyngby, Denmark, [4]National Center for Nano Fabrication and Characterization, Technical University of Denmark, Kgs. Lyngby, Denmark

1133 FLIPs: Novel genetically encoded biosensors for polarization microscopy

Paul Miclea[1], Vendula Nagy Markova[1], Alexey Bondar[1,2,3], Alina Sakhi[4], Dr. Josef Lazar[1]
[1]First Faculty of Medicine, Charles University in Prague, Prague, Czechia, [2]Biological Center CAS, Budweis, Czechia, [3]University of South Bohemia, Budweis, Czechia, [4]Inst. of Organic Chemistry and Biochemistry CAS, Prague, Czechia

1134 Unsupervised and supervised machine learning for feature classification in atomic resolution images

Christian Liebscher[1,2], Andreas Leitherer[3], Byung Chul Yeo[4], Christoph Freysoldt[5], Luca Ghiringhelli[6]
[1]Faculty of Physics and Astronomy, Ruhr University Bochum, Bochum, Germany, [2]Research Center Future Energy Materials and Systems, Ruhr University Bochum, Bochum, Germany, [3]ICFO-Institut de Ciencies Fotoniques, The Barcelona Institute of Science and Technology, 08860 Castelldefels (Barcelona), Spain, [4]Department of Energy Resources Engineering, Pukyong National University, Busan, Republic of Korea, [5]Max-Planck-Institute for Sustainable Materials, Düsseldorf, Germany, [6]Department of Materials Science and Engineering, Friedrich-Alexander Universität, Erlangen-Nürnberg, Germany

1135 Synthesis and Characterization of Ultrathin Unconventional Mixed 2H-HCP/FCC Phase Au Nanowire

Dr. Abhijit Roy[1,2], Dr. Raul Arenal[1,2,3]

[1]Laboratorio de Microscopías Avanzadas (LMA), Universidad de Zaragoza, ZARAGOZA, SPAIN, [2]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, ZARAGOZA, SPAIN, [3]ARAID Foundation Zaragoza , Zaragoza, Spain

1136 Utilization of TEM in archaeology to gain in-depth information on historic artifacts

Lennart Voß[1], Lennart Voss[1], Dr. Ulrich Schürmann[1], Lena Grandin[2], Christian Horn[3], Dr. Khurram Saleem[1], Bruno Vindrola-Padrós[4], Prof. Dr. Lorenz Kienle[1]
[1]Kiel University, Department for Materials Science, Kiel , Germany, [2]The Archaeologists, National Historical Museums, Stockholm/Uppsala, Sweden, [3]University of Gothenburg, , Gothenburg, Sweden, [4]Kiel University, Institute of Prehistory and Early History, Kiel, Germany

1137 INSIHGT - Scalable, Accessible, Homogeneous Deep Multiplexed Immunolabelling Platform for 3D Spatial Biology

Dr Hei Ming Lai[1,2], Mr Jacky Tin Shing Hung[2,3], Mr Juno Chun Ngo Yau[2], Mr King Ngai Chow[2], Mr Thomas Chun Yip Wong[2]
[1]Department of Chemical Pathology, The Chinese University of Hong Kong, Shatin, New Territories,, Hong Kong SAR, China, [2]Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Shatin, New Territories,, Hong Kong SAR, China, [3]Department of Psychiatry, The Chinese University of Hong Kong, Shatin, New Territories,, Hong Kong SAR, China

1138 Nestin expression in the myocardium of normotensive and spontaneously hypertensive rats during aging

Assoc. Prof. Dana Cizkova[1], Assoc. Prof., Ph.D. Jitka M. Zurmanova[2], M.D. Lucie Gerykova[1], Ph.D. Barbara Elsnicova[2], Frantisek Galatik[2], Ph.D. Jan Silhavy[3], Ph.D. Michal Pravenec[3], Prof., M.D., Ph.D. Jaroslav Mokry[1]
[1]Charles University, Faculty of Medicine in Hradec Kralove, Department of Histology and Embryology , Hradec Kralove, Czech Republic, [2]Charles University, Faculty of Science, Department of Physiology, Prague, Czech Republic, [3]Czech Academy of Sciences, Institute of Physiology, Prague, Czech Republic

1139 Studying nano-catalysts degradation with an identical location STEM approach

Dr. Francisco Ruiz Zepeda[1], Lazar Bijelić[1], Armin Hrnjić[1], Ana Rebeka Kamšek[1], Dr Andraž Pavlišič[1], Dr Marjan Bele[1], Dr Primož Jovanovič[1], Dr. Matija Gatalo[1], Dr Milutin Smiljanić[1], Prof. Nejc Hodnik[1]
[1]National Institute of Chemistry, Ljubljana, Slovenia

1140 Visualisation of lepidopteran silk gland morphology using X-ray micro-computed tomography scanning technique

Mgr. Šárka Podlahová[1,2], Mgr., Ph.D. Gabriela Krejčová[1], Mgr., Ph.D. Hana Sehadová[1,2]
[1]University of South Bohemia in České Budějovice, Faculty of Science, České Budějovice, Czech Republic, [2]Biology Centre of the Czech Academy of Sciences, Institute of Entomology, Ceske Budejovice, Czech Republic

1141 TEM structural analysis of photocatalytically active mesoporous single crystalline LaTiO2N particles

Dr. Mont. Jakub Zalesak[1], MSc. Jakob Praxmair[1], MSc. Julian Hörndl[1], Univ.-Prof. Simone Pokrant[1]
[1]Chemistry and Physics of Materials, University of Salzburg, Salzburg, Austria

1142 Correlating microscopy methods: the case of precipitation in lean, bioabsorbable Mg alloys

Dr. Robin Schäublin[1,2], Ms. Tatiana Akhmetshina[1], Dr. Peng Zeng[2], Dr. Stephan Gerstl[1,2], Prof. Jörg Löffler[1]
[1]Department of Materials, ETH Zürich, Zürich, Switzerland, [2]ScopeM, ETH Zürich, Zürich, Switzerland

1143 Imaging Chiral Spin Textures with Electron Interferometry and Polarimetry

Professor Benjamin McMorran[1], Dr. Sergio Montoya[2], Prof. Eric E. Fullerton[2]
[1]University of Oregon, Eugene, USA, [2]Center for Memory and Recording Research, University of California, San Diego, USA

1144 IMG Electron Microscopy Core Facility

Dr Vlada Filimonenko[1,2], Dominik Pinkas[1], Helena Raabová[1], Markéta Dalecká[1]
[1]Core Facility for Electron Microscopy, Institute of Molecular Genetics, Czech Academy of Sciences, , Prague, Czech Republic, [2]Laboratory of Biology of the Cell Nucleus, Institute of Molecular Genetics, Czech Academy of Sciences, Prague, Czech Republic

1145 Interplay between microstructural properties with ionic/electronic conductivity in Na3PS4-based composite cathodes for Na-SSBs

Rana Ucuncuoglu[1], Dr. Leticia Trezecik Silvano[1], Tim Schubert[1], Prof. Dr. Volker Knoblauch[1], Dr Pinar Kaya[1]
[1]Materials Research Institute (IMFAA), Aalen University of Applied Sciences, Aalen, Germany

1146 ESEM technique for monitoring the geo-polymerization mechanism of the wet ash-cement mixture

Phd Bogdan Stefan Vasile[1], Dr. Iulian Boerasu[3], Dr. Adrian-Vasile Surdu[2], Dr. Adrian Ionut Nicoara[2]
[1]Research Center for Advanced Materials, Products and Processes, National University of Science and Technology POLITEHNICA Bucharest, 060042 Bucharest, Romania, Bucharest, Romania, [2]Department of Science and Engineering of Oxide Materials and Nanomaterials, Faculty of Applied Chemistry and Materials Science, University Politehnica of Bucharest, 011061 Bucharest, Romania, Bucharest, Romania, [3]National Research Center for Micro and Nanomaterials, Faculty of Applied Chemistry and Materials Science, University Politehnica of Bucharest, 060042 Bucharest, Romania, Bucharest, Romania

1147 Molecular insights into rapid cell death involving endoplasmic reticulum and nuclear remodeling p

Ms. Samudra Sabari, António Pedro N. B. M. Carneiro, Ines Ambite, Siddharth Chinchankar, Parisa Esmaeili, Prof. Catharina Svanborg, Dr. Arunima Chaudhuri
[1]Lund University, Lund, Sweden

1148 Effects of Myricetin on Mesenchymal Stem Cells Exposed to Oxidative Stress

Prof. Dr. Sibel Köktürk[1], Dr. Mehmet Berker[1], Aysel Bayramova[1], Sibel Doğan[1], Dr. Emel Usta[1], Feride Özdemir[1]
[1]Department of Histology and Embryology, Istanbul University, Istanbul Medical Faculty, İstanbul, İstanbul

1149 Impact of In Situ and Ex Situ Annealing on Al-Cu Heterogeneous Nanostructures: A Comparative Study

Lucia Bajtosova[1], Elena Chocholáková[1], Barbora Kihoulou[1], Jan Hanuš[1], Miroslav Cieslar[1]
[1]Faculty of Mathematics and Physics, Charles University, Ke Karlovu 3,12116, Prague, Czech Republic

1150 The effects of resveratrol on liver damage and ferroptosis in fructose-streptozotocin induced diabetic model

Assoc. Prof Fatma Kaya Dagistanli[1], MSc Mahsa Hoseini[1], MSc Merve Aykac[2], Prof. Dr. Turgut Ulutin[1]
[1]Department of Medical Biology, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Türkiye, [2]Department of Medical Biology, Medical Faculty, Ataturk University , Erzurum, Türkiye

1151 Multiscale characterization of Al-4Fe alloy grown by additive manufactoring

Dr Frédéric Fossard[1], Pauline Stricot[2], Simon Fritz[2], Eric Grevin[1], Maria Tsoutsouva[2], Nicolas Horezan[2], Quentin Barrès[2], Aidar Zakirov[3], Williams Lefebvre[3], Louise Toualbi[2], Yann Le Bouar[1]
[1]Université Paris-Saclay, ONERA, CNRS, LEM, Châtillon, France, [2]Université Paris Saclay, ONERA, Matériaux et Structures, Châtillon, France, [3]Groupe de Physique des Matériaux, Université et INSA de Rouen, UMR CNRS 6634, Rouen, France

1152 Introducing a FAIR RDM infrastructure for electron microscopy and other materials science data

Prof. Christoph Koch[1], Dr. Markus Kühbach[1], Sherjeel Shabih[1], Dr. Sandor Brockhauser[1], Prof. Dr. Erdmann Spiecker[2], Markus Scheidgen[1], Lauri Himanen[1], Ádám Fekete[1], Dr. José A. Márquez[1], Prof. Dr. Heiko Weber[3], Prof. Dr. Claudia Draxl[1]
[1]Department of Physics and CSMB at Humboldt-Universität zu Berlin, Berlin, Germany, [2]Department of Materials Science and Engineering, FAU Friedrich-Alexander-Universität, Erlangen, Germany, [3]Institute of Condensed Matter Physics, FAU Friedrich-Alexander-Universität, Erlangen, Germany

1153 A silicon micro-heater chip for in-situ transmission electron microscopy

Mr. Chen Wei[1]
[1]CNRS/Université Paris-Saclay, Palaiseau, France

1154 Electron Microscopy of a Gas-Atomized NiSiV Powder

Inga Konow[1], Sigurd Wenner[2], Leander Michels[3], Jan Ove Odden[3], Ursula Ludacka[1], Randi Holmestad[1]
[1]Department of Physics, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, [2]Sintef industry, Department og Materials and Nanotechnology, Trondheim, Norway, [3]Elkem, Kristiansand, Norway

1155 Structural investigation of the 40S hnRNP particles

Radka Dopitová[1], Katarina Monkova[1,2], Jiri Novacek[1]
[1]Central European Institute of Technology (CEITEC), Masaryk University, Brno, , [2]National Centre for Biomolecular Research (NCBR), Masaryk University, Brno,

1156 Low-dose cryo-electron ptychography of proteins at sub-nanometer resolution

Berk Kucukoglu[1], Dr. Inayathulla Mohammed[1], Dr. Ricardo C. Guerrero-Ferreira[1,2], Dr. Stephanie M. Ribet[3], Dr. Georgios Varnavides[3,4], Max Leo Leidl[5,6], Dr. Kelvin Lau[7], Dr. Sergey Nazarov[8], Dr. Alexander Myasnikov[8], Dr. Carsten Sachse[5,9,10], Dr. Knut Müller-Caspary[6], Dr. Colin Ophus[3], Dr. Henning Stahlberg[1]
[1]Laboratory of Biological Electron Microscopy, Institute of Physics, SB, EPFL, and Dep. of Fund. Microbiol., Faculty of Biology and Medicine, UNIL, Rt. de la Sorge, Lausanne, Switzerland, [2]Robert P. Apkarian Integrated Electron Microscopy Core, Emory University School of Medicine, 1521 Dickey Drive NE, Atlanta, USA, [3]National Center for Electron Microscopy (NCEM), Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, USA, [4]Miller Institute for Basic Research in Science, University of California, Berkeley, USA, [5]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons (ER-C-3): Structural Biology, Jülich, Germany, [6]Department of Chemistry and Center for NanoScience, Ludwig-Maximilians-Universität München, Butenandstr, München, Germany, [7]Protein Production and Structure Core Facility (PTPSP), School of Life Sciences, Rte 20 Cantonale, Lausanne, Switzerland, [8]Dubochet Center for Imaging Lausanne, EPFL and UNIL, EPFL VPA DCI-Lausanne, Lausanne, Switzerland, [9]Institute for Biological Information Processing (IBI-6): Cellular Structural Biology, Jülich, Germany, [10]Department of Biology Heinrich Heine University, Düsseldorf, Germany

1157 Xenon PFIB-milling and cryo-electron tomography of bacterial anti-phage effectors

Ms Helena Watson[1,2], Dr Casper Berger[1], Professor Malcolm White[3], Professor Laura Spagnolo[2], Dr Michael Grange[1,4], Professor James Naismith[1,4]
[1]Rosalind Franklin Institute, Didcot, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of St Andrews, St Andrews, United Kingdom, [4]University of Oxford, Oxford, United Kingdom

1158 Time ecology method

Marion Bitsch[1]
[1]Turku School of Economics, University of Turku, Turku, Finland

1159 Real-Time Studies of Resistive Switching Mechanisms

Dr. Janghyun Jo[1], Xue Bai[1], Stephan Aussen[2], Sebastian Walford[3], Susanne Hoffmann-Eifert[2], Martin Salinga[3], Rafal E. Dunin-Borkowski[1]

[1]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, Jülich, Germany, [2]Peter Grünberg Institut (PGI-7), Forschungszentrum Jülich, Jülich, Germany, [3]Institute of Materials Physics, University of Münster, Münster, Germany

1160 Visualization of the in situ molecular architecture of tau pathology in the murine brain

Hana Nedozrálová[1], Pavel Křepelka[1], Muhammad Khalid Muhammadi[2], Žilka Norbert Žilka[2], Jozef Hritz[1]
[1]Central European Institute of Technology, Masaryk University, Brno, Czech Republic, [2]Institute of Neuroimmunology, Slovak Academy of Science, Bratislava, Slovakia

1161 Novel scan coil design for high spatiotemporal-resolution imaging in the scanning transmission electron microscope

Mr Adam Phipps[1,2], Dr. Lewys Jones[1,2], Dr. Jonathan Peters[1,2]
[1]Advanced Microscopy Laboratory, CRANN, Dublin, Ireland, [2]School of Physics, Trinity College Dublin, Dublin, Ireland

1162 In-situ cryo-biasing heating TEM sample holder with full-range temperature control from -170°C up to >1000°C

Dr. Calvin Parkin[1], Norman Salmon, Dr. Daan Hein Alsem
[1]Hummingbird Scientific, Lacey, USA

1163 Spatiotemporal observation of ultrafast magnetization dynamics with 4D Lorentz Transmission Electron Microscope

Phd Yuzhu Fan[1], Researcher Gaolong Cao[1], Professor Jonas Weissenrieder[1]
[1]School of Engineering Sciences, KTH Royal Institute of Technology, Stockholm, Sweden

1164 Quantum Measurements using Interferometric STEM-EELS

Professor Benjamin McMorran[1], Dr. Cameron Johnson[1,2], Dr. Amy Turner[1]
[1]Department of Physics, University of Oregon, Eugene, USA, [2]Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, USA

1165 Exploring polar ordering in lead-free K0.5Na0.5NbO3 ferroelectrics using in situ biasing and 4D STEM techniques

prof. Goran Dražić[1,2,3], Ms. Katarina Žiberna[2,3], Dr. Oana Condurache[2,3], prof. Andreja Benčan Golob[2,3]
[1]Department for materials chemistry, National institute of chemistry, Ljubljana, Slovenia, [2]Electronic ceramics department, Jožef Stefan Institute, Ljubljana, Slovenia, [3]Jožef Stefan international postgraduate school, Ljubljana, Slovenia

1166 The use of EELS for the characterization of diamond interfaces: the ohmic contact

PhD Jackeline Valendolf[1]
[1]University of Cadiz, Cadiz, Spain

1167 Large-angle Lorentz 4D-STEM for Simultaneous Magnetic and Atomic Structure Mapping

Dr Sangjun Kang[1], Prof. Xiaoke Mu[1,3], Dr Di Wang[1], Prof Christian Kübel[1]
[1]Tu Darmstadt, Darmstadt, Germany, [2]Karlsruhe Institute of Technology , Karlsruhe , Germany, [3]Lanzhou University, Lanzhou , China

1168 Mapping the Space Charge Region in BaTiO3 and SrTiO3 using 4-Dimensional Scanning Transmission Electron Microscopy

Dr Sangjun Kang[1], Dr Di Wang[2], Dr Dylan Jennings[3], Prof Wolfgang Rheinheimer[4], Prof Christian Kübel[1], Prof Xiaoke Mu[5]
[1]Tu Darmstadt, Darmstadt, Germany, [2]Karlsruhe Institute of Technology , Karlsruhe , Germany, [3]Forschungszentrum Jülich GmbH, Jülich, Germany, [4]University of Stuttgart, Stuttgart, Germany, [5]Lanzhou University, Lanzhou, China

1169

Direct observation of quadrupolar strain fields forming a shear band in metallic glasses

Dr Sangjun Kang[1], Dr Di Wang[2], Prof Xiaoke Mu[3], Prof Christian Kübel[1]
[1]Tu Darmstadt, Darmstadt, Germany, [2]Karlsruhe Institute of Technology , Karlsruhe , Germany, [3]Lanzhou University, Lanzhou , China
1170 CARS microscopy for studies in skin physiology and pharmacology
Professor Jonathan Brewer[1], PhD Irina Iachina[1], MA Lomholt[1], Kim Nielsen[2], Morten Ebbesen[1]
[1]University of Southern Denmark , Odense, Denmark, [2]Leo Pharma, Ballerup, Denmark
1171 Exploring Melanoma Dynamics: Insights from a 3D Cell Culture Model with Vemurafenib Treatment
Rikke Tholstrup[1], Nicoine Dorothea Daugaard[1], Daniela De Zio[2], Jonathan Brewer[1]
[1]University of Southern Denmark, Odense, Denmark, [2]Danish Cancer Institute, Copenhagen, Denmark
1173 Development of an automated pipeline for segmenting and analyzing organelle contacts in Volume Electron Microscopy.
Miss Analle Abuammar[1], Miss Odara Medagedara[1], Mr Aaran Vijayakumaran[1], Mr Vito Mennella[1], Mr Kedar Narayan[2]
[1]University of Cambridge, Cambridge, United Kingdom, [2]National Cancer Institute at NIH center for cancer research, Bethesda , United States
1174 The Impact of Dietary Haemoglobin on Nymphal Stages of I.ricinus: The gut volume EM reconstruction

Mgr., M.sc. František Kitzberger[1,2], RNDr. Ph.D. Veronika Urbanová[1], RNDr. CSc. Petr Kopáček[1], RNDr. Ph.D. Daniel Sojka[1], Mgr. Ph.D. Jan Perner[1], RNDr. Ph.D. Marie Vancová[1]
[1]Institute of Parasitology, Biology Centre of the Czech Academy of Sciences, Ceske Budejovice, Czech Republic, [2]Faculty of Science, Department of Physics, University of South Bohemia, Ceske Budejovice, Czech Republic
1175 In-situ liquid-cell dynamic TEM observations of liquid crystal nanocomposite phase transitions
Ms Olga Kaczmarczyk[1], Katarzyna Matczyszyn[1], Andrzej Żak[1]
[1]Institute of Advanced Materials, Faculty of Chemistry, Wroclaw University of Science and Technology, Wroclaw, Poland
1176 Revealing the molecular architecture of the cell using Ultrastructure Expansion Microscopy (U-ExM)
Prof. Paul Guichard

1177 Precise targeting for volume electron microscopy, a multimodal approach
Mr. Yannick Schwab

1178 Adding Dimensions to Intravital Imaging to Better Eavesdrop on Biology
Professor Scott Fraser[1,2]
[1]Vice President of Science Grant Programs, Chan-Zuckeberg Initiative, , , [2]Elizabeth Garrett Chair of Convergent Bioscience University of Southern California, ,
1179 Dynamics of molecules at the nanoscale: from RESOLFT to STARSS
Ilaria Testa

1180 Mechanics of blastocyst morphogenesis
Jean-Léon Maître

1181 Integrated structural cell biology of pathogen-host interactions
Prof Kay Grünewald

1182 Scanning patterns evaluations towards FIB-SEM/SIMS low-dose high-speed acquisition
Dr Andrés Miranda Martínez[1], Dr. Tom Wirtz[1], Dr. Santhana Eswara[1]
[1]Luxembourg Institute of Science and Technology (LIST), , Luxembourg
1185 Quantification of Potential Drops Across Semiconductor Heterointerfaces Using 4D-STEM: prospects and pitfalls
Prof. Dr. Kerstin Volz

1186 Geological Materials and Bio-mineral systems
Dr David McNamara

1187 Probing the structure and dynamics of active molecular materials with cryo and liquid EM
Professor Joe Patterson

1189 Pushing the limits of Coupled Extreme Environments during In-situ TEM
Professor Khalid Hattar

1190 Exploring the dynamics of semiconductors with an ultrafast transmission electron microscope
Sophie Meuret

1191 Breaking Resolution Limits with Ptychography using Topological Materials
Professor Kayla Nguyen[1]
[1]University of Oregon, Eugene, , United States
1195 Studying the crystallization of inorganic materials using correlated transmission electron microscopy by Brydson et al
Mr. Rik Drummond-Brydson

1196 Exploiting dynamical diffraction theory in the crystal structure determination from 3D electron diffraction data
Dr. Lukas Palatinus

1197 Quantifying nanoscale diffusion phenomena using in situ TEM
Dr. Peter Schweizer

1198 Data analysis workflows to measure material properties and structure using 4D-STEM
Colin Ophus[1], Stephanie Ribet[1], Georgios Varnavides[1,2], Steven Zeltmann[3], Karen Bustillo[1], Alexander Rakowski[1], Benjamin Savitzky[1], Min Chen[2], Yang Yang[2], Andrew Minor[1,2], Mary Scott[1,2]
[1]Lawrence Berkeley National Laboratory, Berkeley, USA, [2]University of California Berkeley, Berkeley, USA, [3]Cornell University, Ithaca, USA
1199 Transdifferentiation of human dental pulp-derived mesenchymal stem cells into neurospheres and transplantation into aganglionic hindgut
Msc Adam Soos[1], MSc. Emoke Szocs[1], Bendeguz Sramko[2], Anna Abbas[2], Dr. Anna Foldes[3], PhD Karolina Pircs[2], Prof. PhD. Nandor Nagy[1]
[1]Department of Anatomy, Histology and Embryology, Semmelweis University, Budapest, Hungary, [2]Institute of Translational Medicine, Semmelweis University, Budapest, Hungary, [3]Department of Oral Biology, Semmelweis University, Budapest, Hungary
1200 Understanding how microalgae cells remediate heavy metals using Atomic Force Microscopy (AFM)
Dr Cécile Formosa-Dague[1], MSc Victoria Passucci[2], Dr Maria Mar Areco[2]

[1]TBI, Université de Toulouse, INSA, INRAE, CNRS, Toulouse, France, [2]IIIA-UNSAM-CONICET, Universidad Nacional de San Martín, Buenos Aires, Argentina

1205 Revealing foliar nanoparticle uptake dynamics: integrating nano-CT, confocal microscopy and LA-ICP-MS insights

Phd Student Andrea Pinna[1], PhD student Emil Visby Østergaard, PostDoc Noemie Thiebaut, Professor Rajmund Mokso, Professor Søren Husted
[1]University of Copenhagen, Copenhagen, Denmark

1206 Streamlining Graphene Liquid Cell Preparation: VitroTEM's Naiad

Mr Hans Radhoe[1], Dr Sina Sadighikia[1]
[1]Vitrotem, Amsterdam, Netherlands

1208 Visualizing electronic correlations in quantum materials at millikelvin temperature

Prof Hermann Suderow[1]
[1]Laboratorio de Bajas Temperaturas y Altos Campos Magnéticos, Departamento de Física de la Materia Condensada, Instituto Nicolás Cabrera and Condensed Matter Physics Center (IFIMAC), Unidad Asociada UAM-CSIC, Universidad Autónoma de Madrid, E-28049 Madrid, Spain

1215 HR STEM study of anion/cation exchange in colloidal lead halide perovskite heterostructures

Iurii Ivanov[1], Mr Nikolaos Livakas[2], Ms Juliette Zito[2], Dr. Ivan Infante[3], Prof. Liberato Manna[2], Dr. Giorgio Divitini[1]
[1]Electron Spectroscopy and Nanoscopy, Istituto Italiano di Tecnologia, , , [2]Nanochemistry, Istituto Italiano di Tecnologia, , , [3]BCMaterials, Basque Center for Materials, Applications, and Nanostructures, Ikerbasque, Basque Foundation for Science, ,

1217 Multi-scale characterisation of laser-induced defects in the production of heterojunction photovoltaic cells

Dr Anacleto Proietti[1], Dr Luca Buccini[1], Dr Pierfrancesco Atanasio[1], Dr. Giancarlo La Penna[1], Dr. Chiara Mancini[1], Dr. Corrado Di Conzo[1,3], Dr. Francesco Mura[1,2], Dr Marco Galiazzo[4], Dr Nicola Frasson[4], Prof. Daniele Passeri[1,2], Prof. Marco Rossi[1,2]
[1]Department of Basic and Applied Sciences for Engineering, Sapienza University of Rome, Rome, Italy, [2]Research Center for Nanotechnology applied to Engineering of Sapienza University of Rome (CNIS), Rome, Italy, [3]Department of Applied Science and Technology (DISAT), Polytechnic of Turin, Turin, Italy, [4]Applied Materials Italia, , Italy

1218 3D imaging, visualisation, and analysis services at Lund University Bioimaging Centre

Dr Sebastian Wasserstrom[1], Dr John Stegmayr[1], Dr Nils Norlin[1]
[1]Lund University Bioimaging Centre, Lund, Sweden

1219 An efficient method for quantifying the degree of neurodegeneration in an insect brain

Jakub Opelka[1,2], Lucie Pauchova[1], Andrea Bednarova[1], Radka Zavodska[1,3], Michal Sery[1,3], Ivo Sauman[1,2], Hana Sehadova[1,2]
[1]Faculty of Science, University of South Bohemia, Ceske Budejovice, Czech Republic, [2]Faculty of Science, University of South Bohemia, Ceske Budejovice, Czech Republic, [3]Faculty of Education, University of South Bohemia, Ceske Budejovice, Czech Republic

1220 Vacuum ultra violet emission spectra observed by newly designed grating with improved diffraction efficiency

Takanori Murano[1], Dr Shogo Koshiya[1], Dr Masaru Takakura[1], Dr Masato Koike[2,3], Professer Masami Terauchi[3]
[1]SA Business Unit, JEOL Ltd., Akishima, Japan, [2]Kansai Institute for Photon Science, National Institutes for Quantum Science and Technology (QST), Kizugawa, Japan, [3]Institute Multidisciplinary Research for Advanced Materials (IMRAM), Tohoku Univ., Sendai, Japan

1221 Visualization of surface plasmon propagation and emissions by cathodoluminescence

Izzah Machfuudzoh[1], Sotatsu Yanagimoto[1], Researcher Naoki Yamamoto[1], Supervisor Takumi Sannomiya[1]
[1]Tokyo Institute of Technology, Yokohama, Japan
1222 Nanocrystals with dilated interplanar distances in the carburized surface case of Inconel-718 gas-processed at 570°C
Dr Corneliu Sarbu[1], Phd Student Marian Cosmin Istrate
[1]National Institute for Materials Physics, Magurele, Romania
1227 Ghostbuster – a phase retrieval diffraction tomography algorithm for cryo-EM particle refinement
Mr Joel Yeo[1,2], Dr. Benedikt Daurer[3], Dr. Deepan Balakrishnan[1], Dr. Dari Kimanius[4], Dr. Tristan Bepler[5], Dr. Yong Zi Tan[1], Dr. Duane Loh[1]
[1]National University of Singapore, Singapore, Singapore, [2]Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [3]Diamond Light Source, Didcot, United Kingdom, [4]CZ Imaging Institute, Redwood City, United States of America, [5]New York Structural Biology Center, New York, United States of America
1228 Heterogeneous dissolution of Au nanoparticles under constant electrochemical potential as observed via in-situ liquid-cell TEM
Dr. Sorour Semsari Parapari[1], Layrton José Souza da Silva[1,2], Miguel Bernal[3], Daniel Torres[3], Dr. Miran Čeh[1,2], Dr. Kristina Žužek[1,2], Dr. Jon Ustarroz[3,4], Dr. Sašo Šturm[1,2]
[1]Jožef Stefan Institute, Department for Nanostructured Materials, Ljubljana, Slovenia, [2]Jožef Stefan International Postgraduate School, Ljubljana, Slovenia, [3]ChemSIN, Université libre de Bruxelles , Brussels, Belgium, [4]Electrochemical and Surface Engineering (SURF), Vrije Universiteit Brussel, Brussels, Belgium
1230 Tracking the Ultrastructure of Life with Serial Block-face Scanning Electron Microscopy
Dr. Alexandra Elli[1], Dr. Nathalie Braun[2], Dr. Dieter Lauer[2]
[1]Carl Zeiss Microscopy GmbH, Jena, Germany, [2]Carl Zeiss Microscopy GmbH, Oberkochen, Germany
1231 Self-assembled nanoparticles in a thin film of water
Dr Crispin Hetherington[1], Dr Dmitry Baranov[2], Dr Katarzyna Makasewicz[3]
[1]nCHREM, Lund University, Lund, Sweden, [2]Chemical Physics and NanoLund, Lund University, Lund, Sweden, [3]Institute for Chemical and Bioengineering, ETH Zürich , Zürich, Switzerland
1232 Structural organization of the native Neisseria meningitids PilQ environment through an MS-EM approach
Dr. David Fernandez-Martinez[1], Dr. Lucienne Nouchikian[2], Sylvie Goussard[1], Prof. Pierre-Yves Renard[3], Dr. Cyrille Sabot[3], Dr. Martial Rey[2], Dr. Julia Chamot-Rooke[2], Dr. Guillaume Dumenil[3]
[1]Institut Pasteur, Université Paris Cité, INSERM UMR1225, Pathogenesis of vascular infections, Paris, France, [2]Institut Pasteur, Université Paris-Cité, CNRS, UAR 2024, Mass Spectrometry for Biology, Paris, France, [3]Univ Rouen Normandie, INSA Rouen Normandie, CNRS, Normandie Univ, COBRA UMR 6014, INC3M FR 3038, Rouen F-76000, France, Rouen, France
1233 Parent grain reconstruction of martensitic microstructures: a comparison of different methods
Dr. Barbara Šetina Batič[1]
[1]Institute of Metals and Technology, Ljubljana, Slovenia
1234 Interactions between Titanium Dioxide Particles and Wood Cell Wall Ultrastructurea
Petr Svora[1,2], Sylwia Krystyna Svorová Pawelkowicz[3], Petra Ecorchard[4], Jan Duchoň[1], Alena Schieberová[5]
[1]FZU-Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic, [2]Czech Technical University in Prague, University Centre for Energy Efficient Building, Buštěhrad, Czech Republic, [3]Institute of Theoretical and Applied Mechanics of the Czech Academy of Sciences, Prague, Czech Republic, [4]Institute of Inorganic Chemistry of the Czech Academy of Sciences, Husinec-Řež, Czech

Republic, [5]Department of Chemistry and Chemical Technologies, Faculty of Wood Sciences and Technology, Technical University in Zvolen, Zvolen, Slovakia

1235 Global BioImaging: Imaging Networks Accelerate Collaboration, Exchange and Innovation in Imaging Science

Dr Yara Reis[1], Dr Gleb Grebnev[1], Dr Deniz Saltukoglu[1], Dr Sophie Winter[1], Dr Antje Keppler[1,2]
[1]Global BioImaging - EMBL, Heidelberg, Germany, [2]Euro-BioImaging - ERIC, Heidelberg, Germany

1236 Visualization of the Endosomal Fate of mRNA-Lipid Nanoparticles Reveals the Reason for Low Escape Rate

Dr. Anke Kaltbeitzel[1], Gunnar Glaßer[1], Dr. Johanna Simon[2], Dr. Eleni Samaridou[2], Dr. Moritz Beck-Broichsitter[2], Kai Speth[1], Prof. Dr. Volker Mailänder[1], Dr. Ingo Lieberwirth[1]
[1]MPI Polymer Research, Mainz, Germany, [2]Merck KGAA, Darmstadt, Germany

1239 3D imaging by Array Tomography using benchtop SEM

Kaori Nakajima[1], Yuuki Yamaguchi[1], Daisuke Masuda[1], Junichi Nakakobaru[2], Motohiro Nakamura[1], Katsuyuki Suzuki[1], Yukari Moriya[1], Yasuyuki Okano[1]
[1]JEOL Ltd., Akishima, JAPAN, [2]SYSTEM IN FRONTIER INC., Tachikawa, JAPAN

1240 Electrochemical sensors for detection of benzotriazole in water

Assist. Prof. Kristina Žagar Soderžnik[1,2], Neža Sodnika[1], Melanija Hadolin[3], Zoran Samardžija[1]
[1]Jožef Stefan Institute, Ljubljana, Slovenia, [2]Jožef Stefan International Postgraduate School, Ljubljana, Slovenia, [3]Faculty of Chemistry and Chemical Technology, Ljubljana, Slovenia

1241 Microstructural characterization of neutron-irradiated ITER specified tungsten grades

Mr Koray Iroc[1,2], Dr. Dmitry Terentyev[1], Dr. Wouter Van Renterghem[1], Dr. Dominique Schryvers[2]
[1]SCKCEN, Mol, Belgium, [2]University of Antwerp, Antwerp, Belgium

1244 Volume Electron Microscopy: A Powerful Tool for Studying Embryonic Pineal Organ Development in Birds

Prof. Bogdan Lewczuk[1], Dr Natalia Szyrynska[1], Dr Magdalena Prusik[1]
[1]University Of Warmia And Mazury In Olsztyn, Olsztyn, Poland

1248 TEM strain measurement methods on SiGe/Si films for accuracy tests

Dr. Roberto Balboni[1], Prof. Matteo Ferroni[1,2], Dr. Fabiola Liscio[1], Dr. Anacleto Proietti[3], Dr. Chiara Mancini[3]
[1]CNR-IMM, Bologna, Italy, [2]University of Brescia, Brescia, Italy, [3]University of La Sapienza, Roma, Italy

1249 FlexAble Labeling of Primary Antibodies with Fluorescent Dyes and Biotin for Multiplex Experiments

PhD Larisa Yurlova[1], Michael Metterlein[1], PhD Longtao Wu[2], XinXing Wang[3], Dr. Christian Linke-Winnebeck[1], Dr. Andrea Buchfellner[1], PhD Lion Lian[3], PhD Deepa Shankar[2], PhD Jason Li[2]
[1]Proteintech Group, Martinsried, Germany, [2]Proteintech Group, Rosemont, USA, [3]Proteintech Group, Wuhan, China

1250 Comparative Analysis of Sample Preparation and Imaging Methods for Metallographic Examination of Archaeological Silver

Dr Alexandra Suvorova[1], Prof Walter Bloom[2]
[1]The University of Western Australia, Perth, Australia, [2]Western Australia Museum, Fremantle, Australia

1251 Phase Transformation of GeO2 Glass to Nanocrystals via High-Temperature Annealing

Dr JIJUN ZHANG[1], Wenshan Chen[2], Thilo Remmele[1], Dr. Hans Tornatzky[2], Dr. Oliver Bierwagen[2], Dr. Dan Zhou[1], Dr. Martin Albrecht[1]
[1]Leibniz - Institut für Kristallzüch, Max-Born-Straße 2, 12489 Berlin, Germany, [2]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117, Berlin, Germany

1253 Computational analysis of the anisotropy of SEM images to quantify nanowire verticality and surface roughness
Eleni Stai[1]
[1]National Centre For Scientific Research Demokritos , Athens, Greece, [2]NKUA Department of Physics, Athens, Greece
1254 Cathodoluminescent and Characteristic X-ray-emissive Rare-Earth-doped Core/Shell Protein Labels for Spectromicroscopic Analysis of Cell Surface Receptors
Sebastian Habermann[1,2], Lukas R. H. Gerken[1,2], Mathieu Kociak[3], Christian Monachon[4], Vera M. Kissling[2], Alexander Gogos[1,2], Inge K. Herrmann[1,2,5,6]
[1]Nanoparticle Systems Engineering Laboratory, Institute of Energy and Process Engineering, Department of Mechanical and Process Engineering, ETH Zurich, Zurich, Switzerland, [2]Laboratory for Particles Biology Interactions, Department Materials Meet Life, Swiss Federal Laboratories for Materials Science and Technology (Empa), St. Gallen, Switzerland, [3]Université Paris-Saclay, CNRS, Laboratoire de Physique des Solides, Orsay, France, [4]Attolight AG, Ecublens, Switzerland, [5]The Ingenuity Lab, University Hospital Balgrist, Balgrist Campus, Zurich, Switzerland, [6]Faculty of Medicine, University of Zurich, Zurich, Switzerland
1255 Observation of spontaneous fluctuations in product selectivity of the acetylene hydrogenation reaction in operando TEM
Dr. Christian Rohner[1], Mr Eugen Stotz[1], Dr. Alexander Steigert[2], Dr. Daniel Amkreutz[2], Prof. Dr. Rutger Schlatmann[2], Prof. Dr. Beatriz Roldan Cuenya[1], PD Dr Thomas Lunkenbein[1]
[1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany, [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany
1256 A systematic study on PtRu alloy composition for catalytic applications
Tonya Kloos[1], Dr. Ningyan Cheng[1], M.Sc. Miquel Vega Paredes[1], M.Sc. Alan Savan[2], Prof. Dr.-Ing. Alfred Ludwig[2], Prof. Dr. Christina Scheu[1]
[1]Max-Planck Institute for Sustainable Materials, Düsseldorf, Germany, [2]Ruhr-Universität Bochum, Bochum, Germany
1257 Correlative light electron microscopy for improved investigation of subcellular GLUT4 distribution in human skeletal muscle
PhD student, MSc Kaspar Wredstrøm Persson[1], Christian T. Voldstedlund[1], Chris Neal[3], Judith M. Mantell[2,3], Erik, A. Richter[1], Paul Verkade[2], Thomas E. Jensen[1]
[1]August Krogh Section for Molecular Physiology, Department of Nutrition Exercise and Sports, University of Copenhagen, Copenhagen, Denmark, [2]School of Biochemistry, University of Bristol, Bristol, UK, [3]Wolfson Bioimaging Facility, University of Bristol, , UK
1258 Synthesis, structural and electrochemical characterization of nanostructured Ir/TiO_2 for the oxygen evolution reaction
Yeeun Bang[1], Dr. Raquel Aymerich Armengol[2], Prof. Dr. Joohyun Lim[3], Prof. Dr. Christina Scheu[1]
[1]Max-Planck-Institute for Sustainable Materials, Düsseldorf, Germany, [2]Technical University of Denmark, Lyngby, Denmark, [3]Kangwon National University, Gangwon-do, South Korea
1259 Insights into the mechanisms of silver phase formation vial electrochemical liquid-cell TEM
Msc. Layrton José Souza Da Silva[1,2], Dr. Sorour Semsari Parapari[1], Monica Parpal Giménez[3], Mohammed El Marini[3], Prof. Dr. Jon Ustarroz[3,4], Prof. Dr. Sašo Šturm[1,2,5]
[1]Department for Nanostructured Materials, Jožef Stefan Institute, Ljubljana, Slovenia, [2]Jožef Stefan International Postgraduate School, Ljubljana, Slovenia, [3]ChemSIN – Chemistry of Surfaces, Interfaces and Nanomaterials, Université Libre de Bruxelles (ULB), , Brussels, Belgium, [4]SURF – Research Group Electrochemical and Surface Engineering, Vrije Universiteit Brussels, Brussels, Belgium, [5]Department of Geology, Faculty of Natural Sciences and Engineering, University of Ljubljana, Ljubljana, Slovenia

1260 Analysis of transcription dynamics via single cell imaging of chemically inducible system in S. Cerevisiae
Yujie Zhong[1], Maximilian Gehri[1], Gamze Dogali[1], Heinz Koeppl[1]
[1]Self-organizing Systems, Darmstadt, Germany
1261 Combining 3D-ED and Z-contrast imaging: crystallographic structure solution of Ca2MnO3Cl
Dr Stéphanie Kodjikian[1], Dr Christophe Lepoittevin[1], Dr Fabio Denis Romero[1]
[1]Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 38000 Grenoble, France
1262 Sub-4-Å cryo-EM structure of apoferritin from a basic 120 keV TEM with thermionic electron gun
Dr. Alexander Neuhaus[1], Dr. Anja Blanque[1], Prof. Dr. Christos Gatsogiannis[1]
[1]Institute for Medical Physics and Biophysics and Center for Soft Nanoscience, Universität Münster, Münster, Germany
1263 Nano-characterization of Sodium-ion cathodes fabricated using economically and environmentally friendly organic routes
Dr Ana M Beltran[1], Dr. Saul Rubio[1], Dr. Francisco J Garcia-Garcia[2], Mr Julio E de la Rosa[2], Dr Eva M. Pérez[2], Dr Isabel Montealegre-Meléndez[1], Dr. Cristina Arévalo[2], Dr. Juan G. Lozano[2]
[1]Departamento de Ingeniería y Ciencia de los Materiales y del Transporte, Escuela Politécnica Superior, Universidad de Sevilla, Sevilla, Spain, [2]Departamento de Ingeniería y Ciencia de los Materiales y del Transporte, Escuela Técnica Superior de Ingeniería, Universidad de Sevilla, Sevilla, Spain
1264 Epitaxial LiNi0.33Mn0.33Co0.33O2 thin films as a model cathode material system for Li-ion batteries
Dr. Elena Tchernychova[1], Blaž Jaklič[2,3], Jan Žuntar[2,3], Gregor Kapun[1,4], Prof. Dr. Matjaž Spreitzer[2], Prof. Dr. Robert Dominko[1,4,5]
[1]National Institute of Chemistry, , Ljubljana, Slovenia, [2]Jozef Stefan Institute, Ljubljana, Slovenia, [3]Jozef Stefan Institute International Postgraduate School, Ljubljana, Slovenia, [4]4Faculty of chemistry and chemical technology, University of Ljubljana, Ljubljana, Slovenia, [5]ALISTORE-European Research Institute, Amiens, France
1265 Investigating VSV-GP replication using TEM & STEM tomography of high pressure frozen, freeze substituted samples
Johannes Georg Wieland[1,2], Rebecca Habisch[1], Dr. Eva Puschmann[1], Dr. Mareike Elvert[1], Prof. Dr. Paul Walther[2], Dr. Jorge Soza Ried[1], Dr. Martin Dass[1]
[1]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Deutschland, [2]Central Facility Electron Microscopy, Ulm University, Ulm, Deutschland
1266 ExpertPI: A Comprehensive Tool for Automated 4D-STEM Multimodal Analysis and Method Development
Mr. Petr Mareš[1], Mr. Vojtěch Homola[1], Dr. Robert Hooley[1], Dr. Zhongbo Li[1], Mr. Branislav Hesko[1], Dr. Daniel Nemecek[1]
[1]TESCAN Group, Brno, Czechia
1267 Fatigue fracture behaviour of high strength steels under gaseous hydrogen
Dr Elina Saarivirta Huttunen[1], Pekka Pohjanne[1], Dr Pekka Moilanen[1], Dr Jouni Alhainan, Dr Supriya Nandy[1]
[1]VTT Technical Research Center of Finland Ltd, , Finland
1269 Understanding of electronic structure by combination of soft X-ray spectrometer with electron energy loss spectrometer
Dr. Cheng Sun[1,2], Dr. Anton Orekhov[2], Dr. Agata Plucienik[2], Dr. Ali Rinaldi[2], M.Sc. Nico Radde[2], Dr. Elena Willinger[2], Prof. Marc-Georg Willinger[2]

[1]TUMint·Energy Research GmbH, Garching, Germany, [2]Technical University of Munich, Garching, Germany

1270 Structural studies of the cross-link mutant, ABC transporter BmrA by cryo electron microscopy

Sepideh Valimehr[1], Margot Di Cesare[2], Elise Kaplan[2], Jean-Michel Jault[2], Cédric Orelle[2], Eric Hanssen[1]
[1]Ian Holmes Imaging Centre and Department of Biochemistry and Pharmacology and ARC Centre for Cryo-Electron Microscopy of Membrane Proteins, Bio21 Institute, University of Melbourne, Melbourne, Australia, [2]Bacterial Nucleotide-Binding Proteins Team, Molecular Microbiology and Structural Biochemistry (MMSB), UMR 5086 CNRS/University of Lyon, Lyon, France

1271 Atomic Structure and Electron Magnetic Circular Dichroism of Individual Rock-Salt Structure Antiphase-Boundaries in Spinel Ferrites

Associate Professor Xiaoyan Zhong[1]
[1]TRACE EM Unit and Department of Materials Science and Engineering, City University of Hong Kong, Kowloon, Hong Kong SAR, China, [2]City University of Hong Kong Matter Science Research Institute (Futian), , Shenzhen, China, [3]Nanomanufacturing Laboratory (NML), City University of Hong Kong Shenzhen Research Institute, Shenzhen , China

1272 Unveiling the Mechanisms of Structural Reconstruction and Magnetic Evolution in NiFe2O4 During Phase Transition

Dr. Qi Wang[1,2,3], Prof. Xiaoyan zHONG[1,2,3]
[1]Department of Materials Science and Engineering, City University of Hong Kong, Hong Kong, People's Republic of China, [2]City University of Hong Kong Matter Science Research Institute (Futian), Shenzhen, People's Republic of China, [3]Nanomanufacturing Laboratory (NML), City University of Hong Kong Shenzhen Research Institute, Shenzhen, People's Republic of China

1273 Understanding and modifying cell wall permeability to facilitate cellular nanoparticle uptake

Tommaso Angeletti[1], Grmay Lilay H[1], Søren Husted[1]
[1]PLEN, Frederiksberg, Denmark

1274 Low energy electron microscopy and spectroscopy of 2D materials

Dr. Eliška Materna Mikmeková[1], Dr Ivo Konvalina[1], Dr. Lukáš Průcha[1], Dr. Ilona Müllerová[1], Dr Aleš Paták[1]
[1]Institute of Scientific Instruments of the CAS, v.v.i., Brno, Czech Republic

1275 Embryonic and postembryonic development of arthropods: imaging from the cellular to the whole organism level

Polona Mrak[1], Urban Bogataj[1], Katja Kunčič[1], Žiga Fišer[1], Miloš Vittori[1], Nada Žnidaršič[1]
[1]University of Ljubljana, Biotechnical Faculty, Department of Biology, Ljubljana, Slovenia

1276 Visualisation of tetrahedral Li in the alkali layers of Li-rich layered oxides

Dr Weixin Song[1,2,3], Dr Miguel Pérez-Osorio[1,2,3], Dr Jun Chen[1,2,3], Mr Zhiyuan Ding[1,3], Dr John Joseph-Marie[1,2,3], Dr Robert House[1,2,3], Prof Peter Bruce[1,2,3], Prof Peter Nellist[1,2,3]
[1]University of Oxford, Oxford, United Kingdom, [2]The Faraday Institution, Oxford, United Kingdom, [3]The Henry Royce Institute, Oxford, UK

1277 Evaluating the Efficacy of Laboratory-Based X-ray Diffraction Tomography for Crystallographic Analysis in Pure Iron

Postdoc Fellow pardis Mohammadpour[1,2], PhD student Mehdi Mosayebi[1,2,3], Research scientist Daniel Paquet[3], Research scientist Pierre-Antony Deschênes[3], Research scientist Laurent Tôn-Thât[3], Facilities Manager Brian Langelier[1], Proffesor Nabil Bassim[1,2]
[1]Canadian Center for Electron Microscopy, Hamilton, Canada, [2]Materials Science and Engineering Department, McMaster University, Hamilton, Canada, [3]Hydro-Québec, Institut de recherche d'Hydro-Québec, Varennes, Canada

1278 Correlative-Cryo Microscopy to Characterise Bacteria-Nanopillar Interactions: Achievements and Challenges
Dr Chiththaka IMIHAMI MUDIYANSELAGE[1], Dr Judith Mantell[2], Dr Angela H. Nobbs[1], Prof. Bo Su[1], Prof. Paul Verkade[3]
[1]Bristol Dental School, University of Bristol, Bristol, United Kingdom, [2]Wolfson Bioimaging Facility, University of Bristol, Bristol, United Kingdom, [3]School of Biochemistry, University of Bristol, Bristol, United Kingdom
1279 3D chromatin architecture by volume EM
Dr. Dusan Cmarko[1], Dr. Pavla Molinova[1], M.Sc. Marketa Dalecka[2], Dr. Ales Benda[3]
[1]Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic, [2]Imaging Methods Core Facility at BIOCEV and Department of Genetics and Microbiology, Faculty of Science, Charles University, Prague, Czech Republic, [3]Imaging Methods Core Facility at BIOCEV, Faculty of Science, Charles University, Prague, Czech Republic
1280 Cryo-EM structure of wild-type Orsay virus: preliminary insights into the assembly mechanism
Dr. Antonela Stagnoli[1], Dr. Victoria G. Castiglioni[2], Technician Ander Vidaurrazaga[1], Dr. Santiago F. Elena F. Elena[2], Dr. Nicola G. Abrescia[1,3]
[1]Structure and Cell Biology of Viruses Lab. Center for Cooperative Research in Biosciences - Basque Research and Technology Alliance (BRTA), Derio , Spain, [2]Institute for Integrative Systems Biology, CSIC-Universitat de València, Paterna, Spain , [3]Ikerbasque, Basque Foundation for Science, Bilbao, Spain
1281 Nanoscale X-ray imaging to Study Bacteria-Nanopillar Interactions
Dr Chiththaka IMIHAMI MUDIYANSELAGE[1], Dr Gulnur Zulpukarova[2], Dr Rafaela Debastiani[3], Prof. Bo Su[1]
[1]Bristol Dental School, University of Bristol, Bristol, United Kingdom, [2]School of Chemistry, University of Bristol, Bristol, United Kingdom, [3]Karlsruhe Institute of Technology, Karlsruhe, Germany
1282 Correlative X-ray and Electron Microscopy Workflow for Investigating Grey Matter Lesions in Multiple Sclerosis
PhD Alexandra Glasmacher-Kober[1], Susann Hesse[1], Prof. Dr. Fred Wouters[1], Dr. Gertrude Bunt[1]
[1]Research Unit Innovative Microscopy Technologies, Institute for Neuropathology, University Medical Center Goettingen, Goettingen, Germany
1284 AI-driven microscopy for analysis of xenotransplantation models
Dr Courtney Wright[1], Professor Deniz Kirik[1]
[1]Brain Repair and Imaging in Neural Systems (B.R.A.I.N.S), Department of Experimental Medicine, Lund University, Sweden, Lund, Sweden
1286 SEM and mCT investigations on GDEs with Copper-Nafion coating for carbon dioxide reduction to ethylene
Dr. rer. nat. Lisa Christine Ehle[1], M. Sc. Vera Ubbenjans[2], Dr. rer. nat. Adrian Mikitisin[1], Prof. Dr. rer. nat. Joachim Mayer[1], Dr. Rer. Nat. Lisa Christine Ehle
[1]Central facility for electron microscopy (GFE), RWTH Aachen University, Aachen, Germany, [2]Chemical Engineering (AVT), RWTH Aachen University, Aachen, Germany
1289 Low-Bleaching Cryo-Light Microscopy with Immersion Objectives Improves Super-Resolution STED Imaging
Niko Faul[1], Maruthi K. Pabba[2], Yujie Zhong[1], Dr. Anja Engel[1], Prof. Dr. Heinz Koeppl[1], Prof. Dr. Cristina Cardoso[2], Prof. Ph.D. Thomas P. Burg[1]
[1]Technical University of Darmstadt, Department of Electrical Engineering and Information Technology, Darmstadt, Germany, [2]Technical University of Darmstadt, Department of Biology, Darmstadt, Germany

1290 Nanosized Ti-Ni composite
Miroslav Cieslar[1], Nikoleta Štaffenová[1], Elena Chochoľáková[1], Jan Fikar[2], Jan Hanuš[1], Lucia Bajtošová[1]
[1]Charles University, Faculty of Mathematics and Physics, Ke Karlovu 5, 121 16, Prague, Czech Republic, [2]2Czech Academy of Sciences, Institute of Physics of Materials, Žižkova 22, 616 00 , Brno, Czech Republic
1291 3D Characterization of Pore Structures in Shaped Heterogeneous Catalysts Using FIB-SEM Tomography
Dr. Aram Yoon[1], Dr. Jaejin Kim[2], Dr. Xiaodan Chen[1]
[1]Shell Energy Transition Campus Amsterdam, Amsterdam, Netherlands, [2]Shell Technology Center Houston, Houston, USA
1294 Cryo-Volume Electron Microscopy characterization of chlorophyll deficient microalgae
Phd Student Malene Olsen[1], PhD Maryna Kobylynska[2,3], Professor Poul Erik Jensen[1], Professor Pippa Hawes[4], Professor Roland Fleck[2,3]
[1]University of Copenhagen, Department of Food Science, Frederiksberg, Denmark, [2]Randall Centre for Cell and Molecular Biophysics, King's College London, London, United Kingdom, [3]Centre for Ultrastructural Imaging, King's College London, , London, United Kingdom, [4]The Francis Crick Institute, London, United Kingdom
1296 Optimized Bright Field STEM Imaging for Detecting Molecules absorbed within Zeolite Pores
Yu Xia[1], Tom Willhammar[1]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden
1298 CELS-3D – Cutting edge light source for exciting fluorescence in microtome-based 3D microscopy
Vladyslav Denyshchenko[1], PhD Christopher Evans[1], Ms Tiina O'Neill[1], PhD Silas O'Toole[1], Clara Scholz, PhD Vladimir Lobaskin[1], Phd Dimitri Scholz[1]
[1]University College Dublin, Dublin, Ireland
1302 Correlative microscopy of graphene with SEM, Raman spectroscopy and AFM
Dr Lok Yi Lee[1], Juliet Biard[1]
[1]Paragraf Ltd, Somersham, United Kingdom
1305 The synthetic chaperonin Poly-CCT5 as a nanoparticle carrier
Mr. Sergio Pipaón[1], Mr. Jorge Gutiérrez[1], Mr. Jesús G. Ovejero[2], Mrs. María del Puerto Morales[2], Mr. Jorge Cuéllar[1], Mr. José María Valpuesta[1]
[1]National Center For Biotechnology (CNB-CSIC), Madrid, Spain, [2]Department of Materials for Health of the Materials Science Institute of Madrid (ICMM), Madrid, Spain
1306 The apoptosome assembly in situ
Calvin Klein[1], Alicia C Borgeaud[1], Michael R Wozny[2], Thomas Lemmin[1], Wanda Kukulski[1]
[1]University Of Bern, Bern, Switzerland, [2]McGill University, Montreal, Canada
1307 Morphology-Driven Photothermal Efficiency in Nanostructured Semiconductors
Dr. Maibelin Rosales[1], Dr. Raynald Gauvin[2], Dr. Andreina García[3], Dr. Senentxu Lanceros-Méndez[1,4]
[1]BCMaterials, Basque Center for Materials, Applications and Nanostructures, Bilbao, Spain, [2]Mining and Materials Engineering Department, McGill University., Montreal, Canada, [3]Advanced Mining Technology Center (AMTC), Universidad de Chile, Santiago, Chile, [4]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain
1312 In situ cryo electron tomography enables localization-dependent structural studies: Finding symmetric nuclear pore complexes

Poster Group 2

Introduction:
Cold plasmas, including glow discharge plasma, are reactive mixtures of charged particles that can be tailored to modify the surface characteristics of materials, without producing unwanted waste. In commercial applications, plasma surface processing is mostly employed to etch silicon for the production of integrated circuits and optical devices. Plasma etching of silicon requires applying a protective mask onto the substrate, followed by subjecting the assembly to a plasma to produce different microstructure such as trenches and channels. Scanning electron microscopy (SEM) allows for high-resolution imaging of the surface morphology of the etched structures, enabling detailed examination of features such as trench profiles, etch depths, and overall surface quality. This analytical technique provides valuable insights into the effectiveness of the etching process and helps in optimizing process parameters for achieving desired patterning outcomes in semiconductor fabrication. Plasma can also etch wood, creating specific microstructures on wood surfaces. Exposure of wood to plasma was shown to be effective in modification of important properties such as surface wettability, permeability and adhesion, thereby removing restrictions on its potential end-uses. However, unlike silicon, the etching process for wood differs due to variations in microstructure and chemical composition both between and within different wood species. Wood has a hierarchical cellular structure consisting of a blend of aromatic (lignin) and aliphatic polymers (cellulose and hemicelluloses, i.e. hollucellulose), and it is reasonable to assume that differential etching of wood will occur when it is exposed to plasma. While SEM has proven to be an excellent approach for studying wood anatomy, its application in detecting plasma-induced changes in cellular ultrastructure and polymeric components at uppermost surface layer of treated wood cell walls is not straightforward. The combination of poor conductivity of wood, difficulties in satisfactory sample preparation and conservation, along with inherent variations in cell wall composition and anatomy restricts the ability to detect such subtle changes. In this research, we conducted a comprehensive scanning electron microscopy study to address these limitations and illustrate how plasma modifies the ultrastructure of cell walls by etching of its polymeric constituents, thereby influencing the surface properties of wood in various applications.
Methods:
Various softwood and hardwood species were selected, and clean defect-free surfaces were meticulously prepared and exposed for prolonged periods of time to a glow discharge plasma generated from water vapor. SEM and chromatic confocal profilometry supplemented with wet chemistry and FTIR analyses were used to examine different cell types and wall layers of wood, and to assess changes in the lignin and holocellulose-derived sugar-content. The thorough high-resolution SEM examinations were conducted to detect if there would be differential etching of wood cell walls because of variation in the susceptibility of their polymeric constituents to degradation by plasma.

We developed a method to quantify the etching of wood cell walls by combining SEM and 3D confocal profilometry, allowing us to examine how applied plasma energy affects the etching of wood cell walls. Performance of plasma-treated surfaces was evaluated by application of coatings and bleaching agents. Additionally, SEM and Environmental Scanning Electron Microscopy (ESEM) were employed to assess the efficacy of plasma in eliminating fungi from infected wood surfaces, and to in situ observe living wood-decaying fungi in the microscope.
Results:
Our approach allowed us to observe that glow discharge plasma etched the cell wall materials at surfaces of wood, commencing by creating voids through etching pits and their membranes and borders in softwoods. SEM revealed that plasma preferentially etched holocellulose (cellulose and hemicellulose), from wood creating lignin-rich surfaces, making it possible to more easily see the distribution of lignin in cell walls. The areas of wood cell walls that were more resistant to etching coincided with regions that that are rich in lignin, for example middle lamella, S3 layer of secondary wall and concentric layers in Homalium. We showed that increased porosity produced by plasma treatment was responsible for greater accessibility of chemical reagents to wood surfaces, and could improve the performance of coatings applied on wood. Furthermore, plasma treatment etched hyphal walls of a blue-stain fungus. Hyphal walls contain chitin, a fibrous polysaccharide similar to cellulose, along with melanins, which are complex, dark-colored polymers. Breakdown of hyphae's walls and removal of melanin enabled the removal of discoloration from blue-stained wood and improved the effectiveness of a bleaching agent. Moreover, in situ ESEM showed promise as a way of revealing the details on modification of wood components by fungi or enzymes at cellular levels.
Conclusions:
Combining scanning electron microscopy with precise sample preparation effectively reveals plasma-induced changes on wood cell walls. This approach permits the detection of differential degradation of wood's cell wall polymers by plasma etching featuring preferential ablation of holocellulose, and higher resistance of lignin-rich cell wall layers. The differential ablation of cell wall polymeric components by plasma, in combination with SEM, could create opportunities to study the cell wall composition and ultrastructure of different plant species or varieties. Etching of pits membranes and borders, followed by ablation of intervening cell wall materials, is the mechanism by which surface porosity of wood increases. This is an interesting phenomenon that should be explored to scale-up plasma processing of wood and other bio-based materials to industrial level.

Investigating Mechanically Interlocking Molecules with the btp [2,6-bis(1,2,3-triazole-4-yl)pyridine] Motif.

Niamh O'Shea[1]
[1]School of Chemistry and Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland, [2]Amber Centre, Crann, Trinity College Dublin, Dublin, Ireland

Poster Group 2

The world of mechanically interlocking molecules (MIMs) has gained providence since the 2016 Nobel Prize Awards, for which Stoddart and Sauvage received the prize for their pioneering work on molecular machines. Rotaxanes are becoming a more and more prominent MIM in the world of mechanostereochemistry due to their versatility and their never-ending potential. Rotaxanes comprise a ring and a dumbbell component; these components are noncovalently bonded, but to break these components apart, a covalent bond must be broken. This project intends to synthesise novel btp [2,6-bis(1,2,3-triazole-4-yl)pyridine] rotaxanes with a twist, as the synthesised rotaxanes will include various lanthanide metals., allowing for investigations through UV visible titrations and confocal microscopy. Previously, the Gunnlaugsson Group have successfully synthesised btp macrocycles and catenanes so that this project will be building on the foundations already laid. A key element to this project is the use of Scanning Electron Microscopy along with Atomic Force Microscopy to view the topology and the morphology of our btp ligands and pseudorotaxanes. Varying our solvents for drop-casting allows for different morphologies and structures to be formed and viewed using microscopy techniques. The work being presented will focus mostly on the results to date but also on the future work and techniques which will need to be implemented to gain a wider landscape of our intended molecules so they can be utilised in day-to-day life. This project aims to produce and create novel interlocking molecule materials for use within the electronic, imaging, and magnetic industries whilst also aiming to utilise these structures in the formation of 'all organic-based redox-active materials for use in batteries.

Nanotubes and Nanostructures of VS_2, WS_2, and MoS_2: Structural Effects on the Hydrogen Evolution Reaction

Maya Bar Sadan[1]
[1]Ben-Gurion University of the Negev, Department of Chemistry, Beer Sheva, Israel

Poster Group 2

Background
Vanadium disulfide (VS_2) emerges as a remarkable functional material, boasting myriad advantages that have propelled its widespread application across various industrial sectors. Its unique electronic and optical properties render it highly desirable for utilization in electronics, optoelectronics, and catalysis. Despite these advantages, the synthesis of VS_2 in specific morphologies, particularly as nanotubes, remains a significant challenge. The complexities associated with preparing various VS_2 nanostructures stem from the intricate control required over reaction conditions, precursor selection, and the delicate balance between promoting specific morphologies and preventing unintended structural transformations. This study aims to overcome these challenges in nanotube synthesis and unlock the full potential of VS_2 in cutting-edge technologies, promising advancements in diverse fields.

Methods
This study describes the preparation of novel VS_2 nanotubes with a unique structure, offering a comparative analysis with benchmark 2D materials MoS_2 and VS_2. The unique VS_2 morphology was explored through electron tomography and compared with VS_2 nanoflowers. Catalytic activity of the various nanotubes and nanoflowers was measured, complemented by a Density Functional Theory (DFT) study to attain a fundamental understanding of the catalytic activity's origin in the materials system. Highly crystalline WS_2 nanotubes and nanotriangles, MoS_2 nanoflowers, and defect-rich MoS_2 nanotubes were synthesized and thoroughly studied for their Hydrogen Evolution Reaction (HER) activity. The synthesis of VS_2 nanostructures depended on the solvent and vanadium precursor, resulting in nanotubes and nanoflowers.

Results
Characterization techniques, including TEM, SEM, powder X-ray diffraction (XRD), and X-ray photoelectron spectroscopy (XPS), confirmed the structures' crystallinity and composition. Electron tomography provided 3D insights into the VS_2 nanoflower and nanotube structures. Electrochemical performance, evaluated through linear sweep voltammetry (LSV) and Tafel analysis, demonstrated that MoS_2 outperformed WS_2 and VS_2, maintaining the catalytic activity order in both acidic and alkaline conditions. Electrochemical impedance spectroscopy (EIS) was employed to evaluate charge transfer resistance (Rct), with MoS_2 nanostructures displaying the smallest Rct. Surface area analysis indicated that MoS_2 nanotubes had the highest electrochemically active surface area (ECSA), attributed to strain and defect-rich surfaces. DFT calculations provided insights into the thermodynamic stability of nanotubes and nanoribbons, with VS_2 nanotubes exhibiting a lower energy of bending than MoS_2 and WS_2. Additionally, DFT calculations on hydrogen adsorption free energy (ΔGH) suggested that VS_2 basal planes have potential catalytic activity, contrary to experimental observations.

Conclusions

In summary, this study presents a comprehensive investigation of various transition metal dichalcogenides (TMD) nanostructures for HER activity. MoS_2 demonstrated superior performance, and despite its metallic-like nature, VS_2 exhibited lower activity. The combination of experimental and theoretical approaches sheds light on the factors influencing TMD catalysis, emphasizing the importance of morphology, defects, and strain in designing efficient electrocatalysts.

Protein imaging in body fluids to understand Alzheimer's disease progression

Peter Nirmalraj[1], Mr Thomas Schneider[2], Mr Ansgar Felbecker[2]
[1]Empa, Zurich, Switzerland, [2]KSSG, St Gallen, Switzerland

IM-09, Lecture Theater 5, august 29, 2024, 14:00 - 16:00

Title: Protein imaging in body fluids to understand Alzheimer's disease progression
Authors: Peter N. Nirmalraj*1, Thomas Schneider2 and Ansgar Felbecker2
Affiliation: Biosensing and Functional Surfaces Group, Transport at Nanoscale Interfaces Laboratory, Swiss Federal Laboratories for Materials Science and Technology (Empa), Dübendorf, CH 8600, Switzerland. 2. Department of Neurology, Cantonal Hospital St. Gallen, St. Gallen, CH 9007, Switzerland.
*: Presenting author
Theme: Protein imaging
Sub-theme: Neurodegenerative diseases
Keywords: atomic force microscopy, biomarkers, Alzheimer's disease, diagnosis
Abstract:
Aims: Alzheimer's disease (AD) is a slow but relentlessly progressing neurocognitive disorders that affects memory and cognition in individuals. The two principal proteins implicated in the pathology of AD are amyloid beta (A β) and tau isoforms whose total content can be quantified in cerebrospinal fluid
(and blood using commercially available biochemical assays. Thus, aggregated forms of A β and tau proteins are emerging as strong candidates as fluid biomarkers to monitor AD onset and progression.
Yet, single particle level differe nces in morphology of these shape shifting proteins in body fluids from
oligomers, and protofibrils to mature fibrils, which are also key indicators of disease stage, remain largely unknown and hence unavailable to clinicians.
Methods: In this talk, I will present results from a proof-of-principle study conducted at Empa in collaboration with neurologists at the cantonal hospital St. Gallen using liquid-based atomic force microscopy (AFM) to resolve and quantify the morphology of protein aggregates at a single particle level adsorbed on red blood cells (RBCs) and those present in CSF from patients at various stages of decline in memory and cognition.
Results: The AFM measurements revealed patient age and stage of neurocognitive disorder dependedependent differences in size, shape, morphology of protein aggregates on RBCs, referred to as physical
biomarkers. The prevalance of pathological fibrils on RBCs when correlated negatively with CSF- A β 42/40 ratio was observed to be significantly higher in A ββ-positive patients. Dense proteins crystals were detected exclusively on RBCs in patients aged 80 years and above, which could be indicators of late stages of AD. Next, we detected direct evidence for protein fibril length to be correlated with AD severity from AFM mapping of CSF from both AD patients and age-matched healthy controls. This new information suggests that ultralong protein fibrils in CSF could be a signature of AD pathology.
Conclusion: The findings highlight the diagnostic relevance of physical biomarkers obtained using nanoscale imaging under standard laboratory conditions. I will also share the next steps in our ongoing efforts to reliably resolve protein aggregates in blood, extract their chemical signature, and

discuss the merits and challenges in validating and integrating physical biomarkers as complementary data that can be used in the clinical diagnosis of AD

Diamond based quantum sensing for detecting stress responses in living cells with subcellular resolution

Mr Arturo Elias-Llumbet, Mrs Aldona Mzyk, Ms Claudia Reyes San Martin, Mrs Nuan Lin, Romana Schirhagl[1]
[1]Groningen University, University Medical Center Groningen, Groningen, Netherlands

Poster Group 1

Diamond based quantum sensing for detecting stress responses in living cells with subcellular resolution

A. Elias Llumbet, N. Lin, A. Mzyk, C. Reyes San Martin, Prof. R. Schirhagl, University Medical Center Groningen,

- Background incl. aims

Free radical generation plays a key role in many different biological processes including cell communication, immune responses or ageing. Since free radical generation also occurs when cells are under stress, it is elevated in many different diseases. Unfortunately, free radicals are short lived and reactive and thus the use of free radical generation as a biomarker is limited.
My group has pioneered using diamond-based quantum sensing to solve this problem.

- Methods

The method is based on NV centers, a defect in diamond, which converts magnetic signals into optical signals. As a result, one can detect signals that are equivalent to T1 in clinical MRI but by optical means with a microscope. Since these signals are easier to detect than small magnetic signals, this technique enables measurements down to the single electron level. In a cellular context that means that we have subcellular resolution at the nanoscale.

- Results

Here I will show data from free radical measurements in living cells. I will further show our first clinical data we obtained with this technique. More specifically, I will show how we can use this technique to measure synovial fluid from arthritis patients and to assess the working mechanism of certain drugs[1]. In the second part of my talk, I will show the results on germ cells where we hope to contribute to a better understanding into male and female infertility.

- Conclusions

We are able to detect free radical generation in living cells with nanoscale resolution

Anisotropic 3-D Dirac Semimetals for Designing Terahertz Sensing Nano-Antennas

Kelvin J. A. Ooi[1]
[1]Xiamen University Malaysia, Sepang, Malaysia

Poster Group 2

Background: The Terahertz frequencies are increasingly becoming an important spectrum for microscopy applications, especially used widely in near-field probes for nanoscale applications. Yet, materials that can interact and enable efficient manipulation of Terahertz radiation is rare. Recently, a class of materials called "Three-dimensional Dirac Semimetals" received widespread attention for their compatibility with the Terahertz frequency regime, such as cadmium arsenide. While the bulk cadmium arsenide is just a semiconductive glass, its topological surface exhibits strong Dirac semimetal properties that has strong interaction with Terahertz electromagnetic waves. We exploit the strong terahertz response of cadmium arsenide's topological surface to design efficient Terahertz metamaterial antennas for microscopy sensing applications.
Methods: First, the topological surface of cadmium arsenide has been modelled as an anisotropic conductive surface using the Fermi-Dirac Kubo formalism. Both linear and nonlinear Terahertz response could be included into the model, as such the potential of parametric amplification microscopy could also be explored. Next, the designs of various metamaterial antenna arrays that could give the highest resonant response as well as largest frequency bandwidth possible has been explored. Geometries of circular, rectangular and triangular - all micrometers in footprint - has been chosen for the designs. Both the structural design and the material properties are input into an electromagnetic solver for simulation. The polarizing ratio between horizontally and vertically-polarized terahertz waves has been used as a performance indicator to measure the ability of the antenna array to distinguish between two different channels of signals. Finally, the nonlinear performance of the antenna arrays is investigated by raising the optical pump intensity to higher levels while observing the corresponding change in the polarizing ratio.
Results: The minimum polarizing ratio of 20 dB is established as the baseline for efficient polarizing sensors. With this standard, it is found that the rectangular-shaped antenna array element gave the best performance in both magnitude and bandwidth. Polarizing ratio of 30 dB and 4 THz bandwidth are achieved for the rectangular-shaped antenna array. As for the nonlinear performance, owing to the high nonlinear Kerr coefficient of cadmium arsenide, moderate pump intensities and power levels of about 10 kW/cm2 are sufficient to modulate the Kerr material refractive index.
Conclusions: Three-dimensional Dirac Semimetals are prospective materials to construct efficient Terahertz sensing nano-antennas for microscopy applications. We have designed Terahertz metamaterial antenna arrays using cadmium arsenide. Polarizing ratios of up to 30 dB and 4 THz bandwidth is achieved using a rectangular-shaped antenna array. On top of that, high Kerr coefficients enabled low pump intensities, which can be used for parametric amplification microscopy techniques.

EELS Compton scattering and the electronic structure of twisted WS2 bi-layers

Alina Talmantaite[1], Yaoshu Xie[2], Assael Cohen[3], Pranab Mohapatra[3], Ariel Ismach[3], Teruyasu Mizoguchi[2], Stewart Clark[1], Budhika Mendis[1]
[1]Dept of Physics, Durham University, , UK, [2]Institute of Industrial Science, University of Tokyo, , Japan, [3]3. Dept. of Materials Science and Engineering, Tel Aviv University, , Israel

PS-10, Lecture Theater 5, august 26, 2024, 15:00 - 16:00

Electronic structure is fundamental to a large class of materials phenomena, including mechanical, optical, magnetic and electronic transport properties. Momentum based spectroscopies such as angle resolved photoemission spectroscopy (ARPES), electron-positron annihilation and Compton scattering are traditionally used to measure the electronic structure. Compton scattering in the transmission electron microscope (TEM) was first explored in the 1980s using electron energy loss spectroscopy (EELS). Despite early success it did not achieve widespread use, largely due to the limitations in EELS spectrometer detector efficiencies, and artefacts arising from Bragg scattering within a crystalline specimen. However, with modern advances in EELS spectrometers as well as computational techniques for modelling dynamical scattering artefacts many of the challenges facing EELS Compton scattering are arguably now resolved. EELS Compton scattering in the TEM provides several benefits over standard X-ray and gamma-ray Compton measurements, such as a higher spatial resolution and the ability to extract useful information from even poly-crystalline materials.

In EELS Compton scattering the incident electron beam undergoes an inelastic collision with individual electrons in the solid. The Compton signal appears as a broad peak in an EELS spectrum acquired at large scattering angles (i.e. high momentum transfer). The width of the Compton profile, which can be as large as several hundred eV, is due to the intrinsic momentum spread of the solid-state electrons. The Compton profile shape is therefore directly related to J(pz), i.e. the density of solid-state electrons with momentum component pz along the scattering vector direction. J(pz) provides a 1D projection of the electronic band structure in reciprocal space. We have applied EELS Compton scattering to examine the electronic structure of bi-layer WS_2, with a twist angle of 18^o between the two layers. The twist angle and the resulting electronic structure is known to control the optical, vibrational and electrical properties of TMD bi-layers. EELS Compton scattering is particularly suitable to this problem, since the low dimensional nature of the WS_2 flakes make it difficult or impossible to analyse the electronic structure using conventional methods.

The J(pz) acquired along the 10-10 reciprocal direction indicates that the electrons are more delocalised in the bi-layer compared to monolayer WS_2. Comparison with density functional theory (DFT) simulations reveal that the delocalization is due to a small amount (i.e. 0.1%) of electronic charge accumulating in the inter-layer region (see figure; electron density is in grey, S atoms in yellow and top and bottom layer W atoms in blue and red respectively). The inter-layer charge accumulates between overlapping W atoms, thereby screening the ‘wrong’ bonds generated by the twist angle. The charge accumulation is also accompanied by a local dilation of the inter-layer spacing. The results uncover the precise nature of twist angle on the electronic and structural properties of bi-layer TMDs.

Role of phonon and plasmon inelastic scattering on Bragg diffracted beam intensities

Budhika Mendis[1]
[1]Dept of Physics, Durham University, , UK

IM-06 (1), Lecture Theater 1, august 29, 2024, 14:00 - 16:00

The strong interaction of an electron beam with matter has enabled 3D electron diffraction of specimens that are otherwise too small for X-ray analysis. For improved crystal structure refinement it is known that the Bragg diffracted beam intensities must be calculated dynamically, rather than kinematically. Inelastic scattering, especially low energy phonon and plasmon excitations with relatively large cross sections, are also unavoidable. Bloch wave models for high energy electron diffraction can however deal with only phonon losses phenomenologically, i.e. thermal diffuse scattering (TDS) is modelled by introducing an imaginary term to the crystal potential, which has the undesirable effect of depleting the electron beam intensity as it propagates through the specimen. Furthermore, there is as yet no method for including plasmons in Bloch wave calculations.

Here Monte Carlo methods are combined with Bloch waves to calculate the inelastic scattering due to phonons and plasmons. The Monte Carlo approach treats the incident electron as a particle, and relies on computer generated random numbers to estimate parameters such as the scattering path length and scattering angles. Since it assumes particle-like behaviour, it is only valid for highly delocalised scattering events such as phonon and plasmon excitations. In such cases the periodic nature of the incident electron in the crystal (i.e. Bloch wave) will be averaged out and therefore has no effect on the scattering. The diffuse scattering is simulated by rigidly shifting the Bragg diffraction spots over reciprocal space; the direction of shift and magnitude of diffuse intensity being determined by the inelastic scattering vector and cross section respectively. Simulated phonon and plasmon diffuse scattering distributions show striking similarities with experiment. For example, the TDS exhibit Kikuchi lines and bands (see figure), while the plasmon diffuse scattering shows ‘halos’ around the Bragg beams. Furthermore, unlike the phenomenological Bloch wave model there is no loss in electron beam intensity due to inelastic scattering.

The new Bloch wave model as well as experiment are used to determine the role of inelastic scattering on Bragg beam intensities. Energy filtered diffraction patterns were acquired from a 1990 Å thick, [110]-Si specimen at single and double plasmon energy losses, as well as at ‘zero’ loss (due to the limited energy resolution energy filtering cannot remove phonon losses). The unscattered beam intensity was found to decrease with increasing energy loss, although the Bragg diffracted beam intensities remained constant within the measurement error. It should be noted that the total intensity for each diffraction pattern was normalised and that no background subtraction was performed, i.e. the diffuse scattering around each Bragg reflection was included in the intensity for that beam. The same trends were also reproduced with the inelastic Bloch wave calculations. For crystal structure refinement the unscattered beam is often ignored and only the relative intensities of the diffracted beams are utilised. Both theory and experiment indicate that the relative intensities are unchanged provided that the diffuse background is not subtracted and correctly assigned to the relevant Bragg reflection. This highlights the importance of the diffuse background in energy unfiltered 3D electron diffraction. To ensure crystal structure refinement is robust to inelastic scattering the diffuse background must be included in the intensity measurements.

Electrochemical lithium intercalation & exfoliation in 2D TMDs and its in-situ studies

Zhiyuan Zeng[1]
[1]Department of Materials Science and Engineering, and State Key Laboratory of Marine Pollution, City University of Hong Kong, Kowloon, Hong Kong

Poster Group 2

We developed a lithium ion battery intercalation & exfoliation method with detailed experimental procedures for the mass production of 11 two dimensional TMDs and inorganic nanosheets, such as MoS2, WS2, TiS2, TaS2, ZrS2, graphene, h-BN, NbSe2, WSe2, Sb2Se3 and Bi2Te3, among them 3 TMDs achieved mono- or double layer yield > 90%. This method involves the electrochemical intercalation of lithium ions into layered inorganic materials and a mild sonication process. The Li insertion can be monitored and finely controlled in the battery testing system, so that the galvanostatic discharge process is stopped at a proper Li content to avoid decomposition of the intercalated compounds. The intercalation strategy can also be used to tune 2D TMDs' physical and chemical properties for various applications. For example, we developed an one-step covalent functionalization method on MoS2 nanosheets for membrane fabrication, which exhibited excellent water desalination performance. For lithium intercalation mechanism, the state-of-the-art In-Situ Liquid Phase TEM is an ideal technique for identifying the phase changes during intercalation process. With self-designed electrochemical liquid cell utilized, we can directly vapture the dynamic electrochemical lithiation and delithiation of electrode in a commercial LiPF6/EC/DEC electrolyte, such as LiF nanocrystal formation, lithium metal dendritic growth, electrolyte decomposition, and solid-electrolyte interface (SEI) formation. Combining with other in-situ techniques, such as in-situ XAS, XRD and Raman, etc, the underlying lithium intercalation mechanism in TMDs were further investigated, which render us a comprehensive understanding of the intrinsic correlation between the intercalation process and TMDs layered structures.

Development of biological specimen preparation methods for electron microscopy using sandwich freezing technique

Masashi Yamaguchi[1], Dr. Azusa takahashi-Nakaguchi, Dr. Hiroji Chibana
[1]Medical Mycology Research Center, Chiba University, Chiba, Japan

Poster Group 1

[Background]
Chemical fixation has been used for observing the ultrastructure of cells and tissues. However, this method does not adequately preserve the ultrastructure of cells; artifacts and extraction of cell contents are usually observed. Rapid freezing is a better alternative for the preservation of cell structure [1, 2]. Sandwich freezing of living yeast or bacteria followed by freeze-substitution has been used for observing the exquisite natural ultrastructure of cells [3, 4]. Recently, sandwich freezing of glutaraldehyde-fixed cultured cells, glutaraldehyde-fixed animal and human tissues, and living plant tissues have also been used to reveal the good ultrastructure of cells and tissues [5, 6]. Here we report the good method to reveal the fine ultrastructure of biological specimens using a sandwich freezing technique and freeze-substitution.

[Methods]
For freeze-substitution of living microorganisms or glutaraldehyde-fixed cultured cells, they were collected by centrifugation and the small amount of concentrated pellet (~0.02 µl) was placed on a copper disk (3 mm in diameter). Another copper disk was covered, picked the disks up with tweezers, and plunged into melting propane.

For freeze-substitution of living plant or glutaraldehyde-fixed animal and human tissues, they were sliced into 0.1 to 0.2 mm thick sections with a razor blade under a stereomicroscope. Place a small drop (~0.02 µl) of 20% BSA or glutaraldehyde solution on a copper disk. Then, use tweezers to place a piece of tissue in the glutaraldehyde on the copper disk, place a 0.1-mm-thick spacer, and cover it with another copper disk. They were plunged into melting propane.

The disks were then detached to expose the specimens in liquid nitrogen, and freeze substituted in acetone containing 2% osmium tetroxide at -80ºC for 2 days. They were embedded in epoxy resin, thin sectioned, stained with uranyl acetate and lead citrate, and observed in JEM-1400 electron microscope (JEOL, Tokyo).

For cryo-electron microscopy of viruses and macromolecules, apply 2 µl of virus or macromolecular suspension (1 mg protein/ml) on the microgrids which were made hydrophilic by treating them by glow discharge (10 Pa, 400 V, 1 mA) using an ion sputter apparatus. Remove excess liquid using filter paper and rapidly freeze the microgrid by plunging them into liquid ethane. Transfer the frozen grids in liquid nitrogen, set in a cryo-transfer holder cooled at liquid nitrogen temperature beforehand, and observe under an electron microscope at low temperature.

For conventional chemical fixation of biological specimens, the sample was fixed in 2.5% glutaraldehyde, post fixed with 1% osmium tetroxide, dehydrated in ethanol series at room temperature, and embedded in epoxy resin. They were thin sectioned, stained with uranyl acetate and lead citrate, and observed in JEM-1400 electron microscope.

[Results]
Figure 1 shows ultrathin sections of chemically fixed (a) and freeze-substituted (b) Escherichia coli (bacteria). By chemical fixation (a), cell walls and plasma membranes were undulated and not

smooth; each ribosome particles cannot be distinguished; so-called DNA area was recognized; and the whole cell body became small and considered to be shrunk. On the other hand, by freeze-substitution after sandwich freezing (the present method, b), cell walls and plasma membranes were smooth; each ribosome particles can be distinguished; so-called DNA area was not present and the whole cytoplasm appear homogeneous; and the whole cell body was not shrunk and appear natural.

Ultrathin sections of living Arabidopsis plant tissues were observed by sandwich freezing and freeze substitution and was found to achieve excellent ultrastructural preservation of cells and tissues. Ribosomes, endoplasmic reticula, nuclei, nuclear membranes, plastids, plastid envelope membranes, mitochondria, vacuoles, and vacuolar membranes were clearly observed. No ice crystal formation was observed in most of the cytoplasm, but small ice crystals were observed in the matrix of the nucleus.

Ultrathin sections of glutaraldehyde-fixed mouse tissues, glutaraldehyde-fixed human tissues, and glutaraldehyde-fixed cultured cells, were observed by sandwich freezing and freeze substitution. Ultrastructure of mouse kidney, heart, liver, pancreas, human skin, white blood cells, and K562 cultured human leukemia cells was clearly observed in natural state at high resolution. They all show excellent ultrastructural preservation, and the plasma membranes, nucleus, nuclear membranes, nuclear pores, nucleolus, mitochondria, Golgi apparatus, ribosomes, microtubules, filaments were clearly observed. No ice crystal formation was recognized and membranes were smooth and not undulated.

Sandwich freezing was also useful for observation of viruses and macromolecules by cryo-electron microscopy. Ice embedded influenza virus and hepatitis B virus core particles have been observed in natural state at high resolution.

[Conclusion]

Sandwich freezing-freeze substitution of biological samples was shown to be a good specimen preparation method by the present study. A new sandwich freezing device has been fabricated and is now commercially available (MW-SFD-01, Marine Work Japan, Ltd, Yokosuka, Japan, http://www.mwj.co.jp/en/). It is useful to rapid-freeze viruses, bacteria, yeast, cultured cells, plant tissues, animal and human tissues. It can freeze plant tissues to as deep as 50 µm, and animal and human tissues to as deep as 0.2 mm if tissues are fixed with glutaraldehyde beforehand. It may be better than HPF machine since it is inexpensive and portable.

Digital Holographic Microscopy of Pseudomonas aeruginosa to Probe Effects of Membrane Active Antimicrobials

Mrs Elizabeth Ison[1,2], Dr Robert P Howlin[3], Dr Ricarda O Hawkins[3], Dr David J Bradshaw[3], Prof Paul Williams[2], Prof Morgan R Alexander[1]
[1]School of Pharmacy, University of Nottingham, Nottingham, United Kingdom, [2]BioDiscovery Institute, University of Nottingham, Nottingham, United Kingdom, [3]Haleon, Weybridge, United Kingdom

LS-02 (1), Lecture Theater 4, august 26, 2024, 10:30 - 12:30

Background: Digital holographic microscopy (DHM) is a unique label-free imaging technique that allows interrogation of a population of individual bacterial trajectories in 3D. An inline-holography approach was taken to discern the effect of the antimicrobial compounds on the motility of the bacterium, Pseudomonas aeruginosa. Bacterial swimming motility depends on membrane-embedded stators that couple an electrochemical gradient with the mechanical rotation of the flagellum. Hence, there is a tight link between the bacterial membrane and motility. We propose that this allows us to use 3D motility changes of P. aeruginosa as a proxy of membrane damage over time, which test by following changes in antimicrobial susceptibility as a function of the bacterial growth phase. Susceptibility to antimicrobials as the upregulation of the alternative sigma factor rpoS could increase resistance as the bacteria enter the stationary growth phase. Antimicrobials were adsorbed to surfaces, exposed to bacteria, and monitored for changes in motility.
Aim: To discern the effects of antimicrobial adsorbed surfaces on bacterial motility using DHM and test whether this links to membrane damage.
Methods: To demonstrate desorption of antimicrobials (chlorhexidine (CHX), cetylpyridinium chloride (CPC), 4-isopropyl-3-methylphenol (IPMP) and formulated (f-CHX)) from the adsorbed surfaces, they were exposed to constitutive light emitting P. aeruginosa CTX::tac'-luxCDABE. Any reduction in bioluminescence is indicative of membrane damage consistent with antimicrobial desorption. The motility profiles of both exponential and stationary growth phase wild type (WT) and rpoS mutant were visualised using DHM with 1000 frame (18 s) image streams being taken every 10 min over 1 h. A 685 nm laser illumination was used and a 20x/0.75 NA objective. Bacteria were tracked using bespoke LABVIEW scripts and reconstructed using MATLAB.
Results: Bioluminescence from the constitutive light emitting P. aeruginosa CTX::tac'-luxCDABE decreased over time with CHX and f-CHX exposure for WT and rpoS cells in both the exponential and stationary growth phase. This corresponded with changes in bacterial trajectories when cells were exposed to CHX and f-CHX which showed increased numbers of sharp turns, quantified as an increase in tortuosity. Stationary WT cells only responded to f-CHX adsorbed surfaces but displayed similar changes in motility. The rpoS mutants displayed increased tortuosity with CHX at both early exponential phase and stationary phase of growth. CPC and IPMP showed no change in luminescence (no deleterious membrane impact) and no change in tortuosity at the concentrations tested.
Conclusions: CHX and f-CHX readily desorb from surfaces, dissipating membrane potential which in turn impacts on bacterial motility. The rpoS gene is important for P. aeruginosa resistance to adsorbed CHX. These motility changes could be discerned through the label-free DHM technique.

Single Crystal Analysis of Nanocrystals by Three-Dimensional Electron Diffraction

Dr. Zhehao Huang[1]
[1]Stockholm University, Stockholm, Sweden

IM-06 (2), Lecture Theater 1, august 30, 2024, 10:30 - 12:30

X-ray diffraction is the predominant method used for structural determination of crystalline materials. However, challenges remain on structural analysis of nanocrystalline materials which are too small to be studied by single crystal X-ray diffraction. Three-dimensional electron diffraction (3DED) has been developed to tackle the challenges. By taking advantages of the strong interaction between electrons and matter, 3DED allows single crystal structural analysis even when the crystal sizes are down to the range of nanometers[1].
In this talk, I will give an overview of the development of low-dose 3DED method for analyzing fragile materials, where we overcome the challenges of electron beam damage to the compounds such as metal-organic frameworks (MOFs) and covalent-organic frameworks (COFs). I will talk about the high-throughput advantage of 3DED on discovery of new MOF materials among phase mixtures[2], and discovery of unknown layer stacking behavior in a 2D COF[3]. By using 3DED, I will further talk about how to probe molecular motions in MOF nanocrystals[4] and study host-guest interactions[5]. Last but not least, I will present our recent development on further reducing electron dose for studying fragile unknown compounds. We believe that using 3DED as a powerful analytical tool for discovering new compounds, and revealing their unique properties at an atomic level would help to accelerate research in physical and life science.

Enhancing Nanomechanical Properties of MXene through Tailored Surface Potential: PFQNM and Kelvin Force Microscopy Studies

Jing Li[1]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden
IM-09, Lecture Theater 5, august 29, 2024, 14:00 - 16:00

2D MXene (Ti3C2TX) possess distinct characteristics such as high electrical conductivity, adjustable surface chemical properties, and mechanical flexibility. These features make them valuable as building blocks for energy storage devices, serving purposes like electrodes, ion transfer regulation, electrocatalysts, and electrodeposition substrates. Enhancing the mechanical strength of MXenes has been achieved by combining them with 1D nanocelluloses from their stable colloidal dispersions. However, the practical application of MXene materials faces obstacles due to their tendency to swell unfavorably caused by weak interactions between nanosheet layers, convoluted pathways for ion transport channels, and susceptibility to oxidation in aquatic environments, consequently impacting the performance of EC devices. The current challenge in optimizing MXene properties is to maintain the EC properties during synthesis. Poly(ionic liquid) treated heterostructure Mexne membranes assembly with layered double hydroxide nanosheets via solution-phase showed high permeability and selectivity, the interaction with the oppositely charged surfaces accerate electrostatic crosslinking between MXene neighboring nanosheets driving the enhanced stability in colloidal phase.1 Up to this point, there has been limited focus on nano-scaled mechanical studies using quantitative peakforce nanomechanical mapping (PFQNM) using a colloidal atomic force microscopy probe to measure the localized mechanical and nano-scaled force origins of HOLO cellulose nanofibers (HOLOCNFs) during interaction with Mxenes in a colloidal phase.

The PFQNM morphology results (Fig. 1.A) revealed a uniform distribution of the HOLOCNF network nanostructure, with HOLOCNFs tightly inserted into Mxene thin sheets. The height distribution of the composite indicated that the integration of HOLOCNFs reduced the roughness of the Mxene, enhancing the overall uniformity of the composite. Specifically, the roughness of the Mxene film (1×1 µm) was measured at 56.8 nm ± 71 pm, while that of the composite was 28.4 nm ± 69 pm. The fitted elasticity modulus (Derjaguin-Muller-Toporov model) for the composite was approximately 132.8 GPa ± 0.39 GPa, compared to approximately 27.6 GPa ± 13 MPa for pure Mxene (Fig. 1.B). The Young's modulus of the composite was approximately four times higher than that of pure Mxene films. Force spectroscopy was employed to quantify the adhesion force between HOLOCNF and the Mxene surface using a HOLOCNF-modified AFM probe (Fig. 1.C and D). Statistical Gaussian fitting of the adhesion force measured during the coated probe's departure (retraction) from the Mxene surface revealed a force that was 10 times stronger (17.2 nN ± 77 pN) than the adhesion force measured for the same Mxene film when a naked probe was used (1.5 nN ± 1.2 pN). These results clearly indicate that the force interaction between nanocelluloses and Mxene originated from Van der Waals attraction, with adhesion being a long-range force at a separation distance of 150 nm. Remarkably, the negative force measured in the force-distance (FD) adhesion region during tip retraction showed a significantly larger dissipation of energy (energy loss) compared to the dissipation observed when a naked probe (solid black curve) was used. The difference in dissipation energy can be attributed to the deformation of the monolayer of HOLOCNF attached to the probe, whereas no layer existed when the Si3N3 surface of the naked probe was measured against Mxene. The force-distance curves unveiled a mechanism of force interaction between the surface of Mxene and the surface of HOLOCNF attached to the AFM probe. The revealed force origin

elucidates the notable colloidal stability of the HOLOCNF-Mxene suspension during its synthesis procedure and provides quantitative information about the strength of attraction force when Mxene film interacts with nanocellulose during the functioning of Mxene films in real time. The strong adhesion force between HOLOCNFs originated from various chemical groups covering the entire nanocelluloses, which were retained during the mild synthesis of HOLOCNF, resulting in robust adhesion force against Mxene during tip retraction. In Fig 1 (E), the localized heterogeneous catalysis mechanisms occurring at the active sites of single layer Mxene and the residual chemical groups on the nanocellulose were in situ visualized by amplitude modulated Kelvin probe force microscopy (KPFM). The decreased surface contact potential (Φ) of the Mxene (1.7 eV) measured after its interaction with the HOLOCNFs in colloidal chemical phase, compare the surface potential of Mxene (4.7 eV). This result revealed the doping mechanism the formation of Ti−O···H− hydrogen bonding between MXene and the chemical groups on HOLOCNFs, which modulated the dipolarity of the MXene surface and thus decreased the work function. The results are agreed with previous report.2 In short, the PFQNM and KPFM results revealed relationship between the structure, nanomechanical and surface chemical properties of Mxene-CNF at a single-fibril level and nanoscale. A future study aims to comprehend the mechanisms involved in electrochemical catalytic reactions in the presence of CO2 using HOLOCNF-Mxenes as electrode in electrolytes.

Elimination of Human Error during CPD Process in Plant Tissue Preparation for Electron Microscopy.

Anna Walkiewicz[1]
[1]Quorum Technologies, Laughton, United Kingdom

Poster Group 1

Critical point drying is a powerful way of removing liquid from a sample without causing damage to its structure. Thanks to the fact that at the critical point both, liquid and gaseous states can coexist, their densities are equal and the surface tension between them is zero, we can transfer molecules from the liquid state to the gaseous state without penalty of changing the appearance of the sample. Its structure will remain intact and thanks to that we can observe samples in Electron Microscopy in the way they appear in their natural state.

Although the principles of critical point drying are simple, the process itself is more complex and requires careful design depending on the sample type. Samples, also require special preparation before undergoing Critical Point Drying. That involves tissue fixation and dehydration in a sequence of solvents like ethanol and acetone.
The tissue fixation procedure is a laborious and long process thus the following step, which is Critical Point Drying, should be free from possible failure.

Wrongly conducted Critical Point Drying can easily lead to sample structure damages, from big to small like structure collapse, shrinkage or just wrinkles. This might result in a disturbance in sample examination or make it completely impossible.
Structure corruption might be avoided by performing the Critical Point Drying process in an automated way, where every step is precisely and automatically controlled. That eliminates human error and gives certainty of the outcome.

Herein we present the influence of parameters on the outcome of plant tissue Critical Point Drying and a way of eliminating human error by designing a dedicated, automated process.
Quorum QDry- an automated Critical Point dryer was used for this study. Plant tissues of a tomato leaf Solanum Lycopersicon and a garden mint leaf Mentha spicata were chosen to present the influence of the amount of solvent-liquid CO_2 exchange cycles, settling time length, heating rate and pressure release rate on the sample structure appearance

SEM-micro-photogrammetry and stereo reconstruction on the Tescan Amber X electron microscope

Evgenii Modin[1], Andrey Chuvilin
[1]CIC NanoGune BRTA, San Sebastian, Spain

IM-01, Lecture Theater 1, august 26, 2024, 14:00 - 16:00

Three-dimensional imaging techniques are widely demanded in various fields including science, medicine, engineering, architecture, and art [1,2]. Combining these techniques with scanning electron microscopy capabilities yields interesting results and extends the capabilities of scanning electron microscopy beyond two-dimensional imaging, opening up new applications.
In our lab, we are exploring the potential of scanning electron microscopy to investigate the three-dimensional surface morphology of a variety of complex objects, from the surface of construction materials to the spatial geometry of micromachined parts and marine organisms.
One of the methods of three-dimensional reconstruction is photogrammetry, which has been actively used in recent decades, especially in the field of geodesy. Another method under study is stereoscopy, which uses a sophisticated algorithm to calculate the surface profile from a pair of images acquired at different tilt angles.
We use automatic data acquisition on the Tescan Amber X instrument thanks to the support of Python scripts (Shark SEM Advanced). It is shown that even quite large objects are suitable for correct scanning without the need for image stitching. Further, the Structure from Motion photogrammetry methodology implemented in AliceVision Meshroom and AgiSoft Metashape software packages is used to calculate three-dimensional models. However, it should be noted that this method requires not only an accurate dataset, but also significant computational resources. Ongoing work in this area explores the use of neural network-based neural radiance fields (NERFs) for on-the-fly reconstruction [3].
The stereoscopic method reconstructs the surface profile from two photographs taken at different sample angles, typically ±5 degrees or close to it. Unlike the implemented algorithms available in the literature and well-known commercial packages, our software can use gigapixel images, allowing the characterization of millimeter-scale regions with nanometer resolution and thus meeting and exceeding the ISO 4287-1997 standard in surface topography characterization.

Development state of the CEOS ground-potential monochromator

Felix Börrnert[1], Stephan Uhlemann[1], Heiko Müller[1], Volker Gerheim[1], Klaus Hessenauer[1], Holger Schulz[1], Maximilian Haider[1]
[1]CEOS GmbH, Heidelberg, Germany

IM-04 (1), Lecture Theater 1, august 27, 2024, 10:30 - 12:30

Electron energy loss spectroscopy (EELS) is a long established analytical method to investigate the chemistry as well as the electronic and optical properties of materials. There are several kinds of EELS, namely regards the energy of the primary electrons and if the geometry is in transmission or reflection. Each method provides distinct information about the sample. In particular, EELS often is integrated into an electron microscope adding spatial information to the spectroscopic signal with about the spatial resolution of the hosting microscope. In this respect, EELS in transmission at primary electron energies in the order of several 10 keV and above gained much popularity in the last decades due to the success of (scanning) transmission electron microscopy ((S)TEM). It evolved into a widespread characterisation method being able to deliver spectroscopic information at the atomic level.

The energy resolving power in modern instruments is often sufficient for just identifying the elemental composition of a material by absorption edge onset fingerprinting, and in many cases the respective bonding states can be investigated by looking at the edge fine structure. Nevertheless, a higher energy resolution would help to find very weak signals and make the fine structure less ambiguous. More importantly, a better energy resolution gives access to very small energy loss signals that otherwise would be shadowed by the fringe of the primary electron beam signal. There, most interesting information about the physical properties of the investigated specimen can be gained.

In spectroscopy using electrons, the energy distribution of the primary electron beam ΔE_0 is a major limiting factor for the energy resolving power of the spectrometer. Reducing ΔE_0 by means of a monochromator can enhance the energy resolving power of the system accordingly. Additionally, in (S)TEM, ΔE_0 in conjunction with the chromatic aberration of the imaging system is one of the limiting factors for the maximum spatial information transfer, especially at lower energies. Therefore, a monochromator can also help to enhance the spatial resolving power of (S)TEM instruments.

There are different types of electron monochromators; crossed electric and magnetic fields, called Wien filter or trochoidal monochromator, and electric or magnetic sector fields (prisms) combined in various geometries (α- or Ω-shaped, hemispheres, or using electron mirrors), leaving out more exotic schemes like radio frequency cavities for pulsed electron beams. To date, four different types of electron monochromators for (S)TEM instruments have been commercialised. First, the simple single-stage Wien filter and second, the more advanced double-stage Wien filter, both employing crossed electric and magnetic multipole fields and a straight optical axis. Third, the purely-electro-static Ω-monochromator using inhomogeneous sector fields bending the optical axis into an Ω-shape and fourth, the purely magneto-static ground-potential monochromator combining magnetic sector fields in such a way that the optical axis follows an α-shaped trajectory. For the first three cases the monochromator is added before the accelerator at low electron energies or at high potential. The fourth implementation is different in this respect. Here, the monochromator is added after the

accelerator at high electron energies or at ground potential. The latter implementation ties in with earlier concepts from electron spectroscopy, where the energy-filtered source and the energy analyser are at the same potential. In that case, only the interaction with the specimen causes energy differences and disturbing effects from instabilities of the accelerator can be avoided. Moreover, having the monochromator, the spectrometer and the specimen at ground potential is very beneficial from a technological point of view since additional high-tension feed-through and energy transfer are not necessary. Recently, with a ground-potential monochromator implemented in a dedicated STEM, an unprecedented energy-resolution has been demonstrated and employed for phonon and aloof-beam plasmon spectroscopy. All four presently used monochromator implementations have in common, that the optical design are orthogonal systems with single-section symmetry, that is, the optical axis and the dispersive trajectories are all situated in one section. The optical axis can be curved in one section but not in two sections as long as a perfectly manufactured system without tolerances is considered.

In this contribution, we present the development state of our new design of a ground-potential monochromator based on magnetic prisms in a three-dimensional arrangement. This design abandons the energy selection at the central symmetry plane and the optical axis is not only curved in one section but in two sections. This allows for a highly symmetric and compact design with a variable energy window but no mechanically adjustable energy-filtering slits. Fixed blocking blades in combination with optical deflectors reside at distinct dispersive planes making the system robust and flexible. The practical design fits primary electron energies from 30 keV up to 300 keV and provides an energy resolving power of better than 2·10−7 with respect to the primary electron energy. Also, the resulting beam cross-over after the monochromator is free of residual spatial or angular dispersion. Very importantly, the new monochromator is designed to be potentially retro-fittable to existing microscopes, adding about 33 cm to the total height of the microscope column.

Miniaturized material testing devices for multimodal in situ microscopic studies

Matthias Weber[1], Dr. Julian Müller[1], Dr. Rainer Steinheimer[2], Prof. Robert Brandt[3], Prof. Axel von Hehl[4], Prof. Benjamin Butz[1]
[1]Micro- and Nanoanalytics Group, University of Siegen, Siegen, Germany, [2]Lehrstuhl für Umformtechnik, University of Siegen, Siegen, Germany, [3]Lehrstuhl für Werkstoffsysteme für den Fahrzeugleichtbau, University of Siegen, Siegen, Germany, [4]Lehrstuhl für Materialkunde und Werkstoffprüfung, University of Siegen, Siegen, Germany

Poster Group 2

To contribute to the understanding of failure and fatigue, we examine the local microstructural strain/stress peaking as well as crack initiation/propagation by in situ methodology. Moreover, systematic errors in load/displacement of the measuring setup may be overcome by highly localized strain measurements, e.g. high-resolution EBSD in conjunction with image correlation. This requires in situ material tests, and we aim at two complementary goals. One is to contribute to alloy development and to optimize microstructure of selected alloys determining the macroscopic mechanical properties.
The second is to validate modern microstructure-based FEM simulations and to develop termination criteria for classical FEM simulations, e.g. for crack initiation. Therefore, the Mechanical Engineering Department develops in situ testing machines for static and dynamic tests. Latest developments are a portable, miniaturized 3-point bending machine for use in FIB/SEM/XRD (Fig. 1 a). Thos enable the direct observation of microstructural changes like crack initiation/propagation, as well as phase transformations, e.g. in steels. As an example, the bending machine (750g, 100x100x50mm) with independent load/displacement sensors allows for massive plastic deformation at loads up to 4kN. Our solution includes a user-friendly interface to lower the entry barriers for beginners (Fig. 1 c). In this contribution, we highlight the possibilities to observe dynamics of crack initiation/propagation, phase transformations, and the local evolution of the microstructure during testing of materials like Al alloys and austenitic steel. Electron backscatter diffraction (EBSD) is employed to in detail understand the crystallographic structure adjacent to the crack (Fig. 1 b). Direct image correlation is used to examine local strain peaking. Future plans involve establishing high-resolution EBSD instrumentation and data analysis for highly localized strain/stress/GND mapping as well as corresponding XRD data during a single experiment.

Using the YOLO DeepLearning algorithm to quantify the rAAV empty/filled ratio from Cryo-EM imaging

Manon Mirgaux[1], William Amadou[1], Louise Conrard[1], Egor Zindy[1], Ayse Betul Oktay[1], Professor David Perez-Morga[1], Professor Olivier Debeir[1]
[1]Université Libre de Bruxelles, Gosselies, Belgium

Poster Group 1

Recognized as one of the most common vehicles for gene therapy, rAAVs offer numerous advantages such as low pathogenicity, the ability to precisely redistribute the genome, high tissue dispersal, high infectivity, and long-term persistence in cells [1, 2, 3]. The rAAVs are small (25 nm diameter), single-stranded DNA parvoviruses that are non-infectious for humans [4]. Their capsids are made up of an assembly of 60 viral proteins with icosahedral symmetry and contains the genome. When the rAAV enters the cell, it releases the genetic material contained in the capsid, leading to gene therapy treatment. At present, the rAAV production methods used for clinical trials inevitably lead to a mixture of empty and filled virions, present in varying proportions [5]. Consequently, empty vectors (without genetic material) or vectors with erroneous genetic information (partial or double genetic material) co-exist with vectors containing the correct genetic information (called filled vectors). These empty vectors are unable to provide therapeutic effect and acts as an impurity that can generate an immune response or inhibiting transduction, while partially/doubled filled vectors can cause a dysfunctional gene and lead to side effects. It is therefore important for pharmaceutical research to quantify the empty/filled ratio before bringing a drug to market. [6]

There are several ancestral characterization methods for integrity analyses and the quantification of empty/full ratio of rAAVs. Among these methods, cryo-EM microscopy is of particular interest for quantification, as it enables particles to be visualized without the addition of dyes. The contrast is therefore linked to the atomic composition of the particles: the presence of the genome means that filled particles are more contrasted, as empty and intermediate classes can then be determined. To use the power of cryo-EM to determine the level of empty and filled capsids, it is important to develop software tools for post-acquisition image processing. This tool development faces several challenges stemming from the nature of cryo-EM imaging. Sample purity, cryo-plunging conditions, spatial projection and acquisition parameters are all variable parameters that explain the difficulty of development of computer-aided detection methods for accurate capsid detection. As a result, many parameters such as contrast, size, gray scale values and texture must be defined by the user, given the dependence of these characteristics on image background noise and image quality.

In this study, we present a new home-made method for detecting and quantification of empty/full ratio of rAAV capsides in cryo-TEM images. First, the capsides are detected with a popular deep learning architecture, YOLO. Then, the detected rAAVs are analysed according to their image intensity projections and assigned a fullness score. The accuracy of this methodology is then compared to Relion determination, depending on various factors including sample purity, concentration, batch or even variation in plunging and acquisition conditions. These new methodological developments open the door to faster, more precise quantification of rAAVs for pharmaceutical research.

The behavior of additive manufactured aluminum alloys upon anodization

Lydia Daum[1], Dr. Stefan Ostendorp[1], Dr. Martin Peterlechner[2], Prof. Dr. Gerhard Wilde[1]
[1]Institute of Materials Physics, University of Münster, Münster, Germany, [2]Laboratory of Electron Microscopy, Karlsruhe Institute of Technology, Karlsruhe, Germany

Poster Group 1

Background incl. aims
Additive manufacturing of aluminum alloys, i.e. laser powder bed fusion (3D printing), introduces significant versatility and innovation to various industrial applications. Al-Fe-Zr alloys, which are suitable for additive manufacturing, exhibit mechanical properties comparable to conventionally cast aluminum alloys that are alloyed with Mg, Mn and Si, such as the 60xx series Al-alloys. Anodization of aluminum alloys is performed to enhance their chemical and mechanical performance by the formation of a protective anodic aluminum oxide (AAO) layer. The absence of those 60xx series alloying elements in Al-Zr-Fe, which typically form voids in AAOs and alter the structural integrity, suggest a distinct anodization behavior. This might lead to improved chemical and mechanical properties of the grown passivation layer.
Additionally, the overall microstructure of 3D printed alloys inherently differs from conventionally casted, processed and artificially aged microstructures of the same alloy. Here, a variety of elongated and equiaxed grains are observable along the printing direction. This disparity underscores the necessity for a comprehensive comparison of differently treated microstructures prior to anodization. Afterwards, the anodization behavior of Zr- and Fe-enriched precipitates are investigated to ascertain their impact on the chemical resistivity of the resulting AAOs.
Methods
The microstructure of the Al-Fe-Zr alloy was modified through changes in the manufacturing method, varying degrees of severe plastic deformation and adjustments to the heat treatment before anodization. Polished sample surfaces are analyzed with EBSD and subsequently anodized under galvanostatic conditions in oxalic acid solutions following a standardized protocol which allows to determine the impact of different precipitates' sizes and electrochemical potentials. All AAO-coated samples are bisected using a wire saw, which each half treated independently thereafter. The first half is directly coated with Cr/Au to enhance electron conductivity for TEM lamella preparation in FIB whereas the other half was exposed to reactive ion etching to study the chemical resistivity of the AAO.
TEM samples are prepared by employing Ga-, Si/Au- or He/Ne-FIB on randomized surface positions. The AAOs were analyzed in a Gatan Double Tilt LN2 Cooling Holder 636 using a Titan Themis 60 – 300 operated at 300 kV and at a temperature of 96 K. EDX spectra are recorded with a quadrupole SuperXG2 detector. A CCD-GIF camera is used to record nano-beam diffraction patterns (NBDPs), also denoted as 4D-STEM. Beam damage is suppressed by using beam currents as low as 10 pA during NBDP acquisition.
Results
Given the difference of current densities during anodization of various types of microstructures while maintaining the standardized protocol, the analysis of various NBDPs of different precipitates – each with a stack size of at least 10000 NBDPs – suggests a size-dependent anodization behavior of Fe-enriched precipitates and underscores the influence of the underlying microstructure and the participating precipitates on the grown AAO thickness. Using 4D-STEM and fluctuation electron microscopy, various oxide types within the AAO were distinguished and information about the

precipitates' structure and chemistry are correlated, which supports the hypothesis of size- and type dependent influence. Ga-contamination due to FIB preparation at grain and phase boundaries was diminished by changing to Si/Au or He/Ne FIB for the final polishing step. Finally, we attribute the microscopic differences in AAO growth to macroscopic properties such as chemical resistivity.
Conclusions
Based on the results, Fe-rich precipitates remain partially unaffected by anodization, depending on their size and type, while Zr-rich ones are anodized with the matrix. Unlike conventional alloys, Al-Zr-Fe alloys do not develop voids within the AAO, which leads to a distinct chemical resistivity. Moreover, the microstructure is affecting the properties of the AAO. This emphasizes the importance of selecting an advantageous microstructure tailored to the intended application of the protective layer.

Local mobility and atomic structure in Pd- and Zr-based bulk metallic glasses

Olivia Vaerst[1], Dr Harald Rösner[1], Dr Martin Peterlechner[2], Prof Dr Gerhard Wilde[1]
[1]University of Münster, Institute of Materials Physics, Münster, Germany, [2]Karlsruhe Institute of Technology, Laboratory for Electron Microscopy , Karlsruhe, Germany

Poster Group 2

Background incl. aims
Metallic glasses are a category of materials not completely understood yet. Especially the glass transition mechanisms and the origin of structure-property relations are unclear and gaining deeper insights is of great interest. With a detailed analysis of the local structure and atomic mobility in two model systems of bulk metallic glasses, the possibility of observing atomic processes that govern basic glassy mechanisms can be sought after.
Methods
The here investigated Pd- and Zr-based materials are model glass systems with high kinetic stability and superior mechanical properties, respectively. They are prepared by copper mould casting and verified for their amorphous phase by X-ray diffraction. Further characterisation in terms of thermal properties is done by differential scanning calorimetry. Microstructural investigations are based on electron microscopy techniques: In TEM mode, the method of Electron Correlation Microscopy (ECM) is used to probe the local dynamics and structural relaxation times of Pd- and Zr-based metallic glasses. ECM gives further insights into the underlying mechanisms of amorphous phases with nanometer spatial resolution. Experiments are performed both at room temperature and elevated temperatures using FIB-prepared lamella with a Protochips Fusion AX in situ heating holder. Complementary structural investigations concerning the medium range order (MRO) in glassy metals are performed by 4D-STEM fluctuation electron microscopy (FEM), evaluating the normalized variance of speckles in nanobeam diffraction patterns.
Results
ECM yields a structural relaxation time and a stretching exponent from fits to intensity correlations of dark-field images over time. The structural relaxation time is a measure of local mobility in the material and was found to be different for the two investigated material systems, attributed to their different compositions. In addition, the two material systems react differently to the electron beam during the ECM measurements, where the determined stretching exponent might help to understand the underlying dynamics mechanisms in more detail. Comparisons of ECM-determined parameters from room temperature experiments and measurements at elevated temperatures also show a difference between the two material systems, which are connected to the thermal stabilities of each metallic glass. Moreover, the MRO investigated by fluctuation electron microscopy shows different MRO sizes and volume fractions for the two material systems. A comparison of these findings with thermal parameters resulting from macroscopic measurements is performed.
Conclusion
The conducted investigations show clear differences between the two material systems in the local dynamics as well as the atomic structure. These deeper microstructural insights from electron microscopy measurements at various, also elevated temperatures complement the results of macroscopically averaging methods of thermal and mechanical investigations. Combining the findings allows to better understand the glassy state and beam-induced dynamics including underlying mechanisms.

Poster Group 1

Functional nanostructures are often transformed through gas-based processes such as restructuring, oxidation, and sublimation. This process is called plasma-less gas-phase etching and is particularly important to achieve damaged-free sub-10-nm metal recess to facilitate the integration of metal interconnects with upcoming logic or memory components, crucial for advancing future microelectronic devices towards higher performance and miniaturization. The process involves gas-phase oxidation and subsequent sublimation where the liquid phase etching usually struggles due to poor diffusion in deep and narrow trenches. Furthermore, it provides precise depth control and reduced sidewall damage, making it advantageous over plasma-based or liquid chemical etching for metal recess or etching narrow trenches in microelectronics. However, understanding the detailed dynamic pathways of these transformation processes in gas environments is lacking, yet it is crucial for optimizing such etching techniques. In this work, we tracked the details of a densely packed 32-nm-wide Mo-metal lines recess by using the gas-phase in-situ TEM method. Specifically, the nanoscale modifications in the densely packed 32-nm-wide Mo-lines induced by the gas environments were observed in real-time. In this talk, I will discuss some of this research exploring the previously unknown intermediate steps of the restructuring of Mo-lines under a gas environment. The obtained dynamic insights possess a great impact on the development of semiconductor nanodevices.

Single particle CryoEM structures using iDPC-STEM from 4D-STEM detectors at near-atomic resolution

Daniel Mann[1], Aikaterini Filopoulou[1], Max Leo Leidl[1,4], Mr Maarten Wirix[2], Mr Ivan Lazic[2], Knut Mueller-Caspary[4], Mr. Carsten Sachse[1,3]
[1]Ernst Ruska Centre 3, Forschungszentrum Juelich, Juelich, Germany, [2]Thermo Fisher Scientific, Eindhoven, Netherlands, [3]Heinrich Heine University, Duesseldorf, Germany, [4]Ludwig Maximilian University, Munich, Germany

IM-11 (1), Lecture Theater 5, august 29, 2024, 10:30 - 12:30

CryoSTEM can image frozen-embedded biomolecules in focus without an oscillating contrast transfer function, enabling complete information transfer in each image. Using integrated differential phase contrast (iDPC)-STEM, one can obtain three-dimensional reconstructions of proteins using single particle analysis. We have recently demonstrated how iDPC-STEM can be used to reconstruct protein structures to near atomic resolution (Lazic et al. Nat.Meth. 2022), depending on the chosen convergence semi angle (CSA) of the incident beam. During scanning the electron dose rate is orders of magnitude higher compared to parallel illumination as the dose is distributed in a very small area (Ang2) and for a very short time (50 ns – 10 µs). We compare beam damage of conventional TEM and iDPC-STEM on the same frozen-embedded protein sample. We will demonstrate how this technique can be further applied to a variety of test samples and how alternative ptychographic image reconstruction methods such as single side band (SSB) can be used to further enhance the image information.
iDPC-STEM using segmented detectors is an approximation for integrated center of mass (iCOM) reconstructions. Therefore, we recorded pixelated 4D-STEM data of frozen-embedded protein molecules with a 300 kV Titan Krios G4i equipped with a fast pixelated 4D-STEM detector (Dectris Arina), derived the corresponding iCOM images and reconstructed protein structures to near-atomic resolution.

The Best of Both Worlds: Combining Label Free and Fluorescence Imaging with Livecyte

Peter Djali[1], Dr Meetal Jotangia[1]
[1]Phase Focus Ltd, Sheffield, United Kingdom

Poster Group 1

Fluorescent imaging can reveal much about cellular function but can also be a double-edged sword with both phototoxic and cytotoxic consequences that can impair normal cell function or even induce cell death. Livecyte's label-free live-cell imaging is a powerful quantitative phase technique, generating high-contrast, fluorescence-like images using low powered illumination in which cells appear as bright objects on a dark background. The enhanced contrast increases the robustness of single-cell segmentation and tracking without the need for dyes, maintaining true physiological conditions over a long period of time. Additionally, Livecyte offers the best of both worlds: - intermittent fluorescence imaging reduces the potential detrimental effects and can be linked to the more frequent non-perturbing label-free images.

Our previous studies have reported the detrimental effects to normal cell division of the nuclear live-cell imaging stain SiR-DNA when compared with non-perturbing label free imaging on the Livecyte. The inclusion of SiR-DNA reduced both cell count and total dry mass in a LED power dose-dependent manner relative to non-illuminated and unlabelled conditions suggesting fluorescence altered cells natural growth and proliferation rate. Alongside this, SiR-DNA and illumination increased median cell area which correlated with changes in average dry mass per cell compared to controls. Being able to look at multiple parameters indicates a cell profile of phototoxicity with slowed division and accumulation of mass leading to a large, oversized phenotype.

Such effects will be even more enhanced when dealing with sensitive primary cells such as T-Cells and Neuronal cells. We now show how we can track neuronal outgrowth completely label free, by a unique combination of brightfield and Livecyte label free technique, and how an advanced T-Cell assay can be built in which the sensitive primary effector cells remain entirely label free.

T cell killing assays traditionally yield little or no information on the T to Target interactions and would rely on fluorescence labelling of photo vulnerable primary T cells. However, Livecyte can gain a plethora of T cell interaction kinetics with target cells including the time and number of T cell contacts with a target cell before cell death occurred. All of this without having to label T cells giving more meaningful insights on how your engineered T cells are behaving and more predictive information for in vivo studies.

Livecyte's label free imaging and analysis has also set a new precedence for neurite outgrowth assays. Neuronal cells are also more at risk of phototoxicity limiting our ability to image over long periods of time and to look at network formation dynamically. With Livecyte's advanced analysis recipe, neurite outgrowth can be quantified from the initial changes in cell morphology and migration as cells form attachments through to network formation and metrics such as the number of branching points and total neurite length, gaining a novel understanding of the effect of therapeutic drugs on the dynamics of neurite outgrowth.

There is mounting evidence revealing multiple off-target effects and phototoxicity caused by fluorescence excitation probes with reactive oxygen species being the predominant cause of phototoxicity [1,2]. Livecyte versatility enables either non-invasive QPI only or with a possibility of intermittent fluorescence imaging producing a plethora of time sensitive single-cell information where there is a strong need to protect the cells. This provides invaluable data to researchers using fluorescence to investigate subtle changes in cell behaviour and phenotype.

The Electron Bio-Imaging Centre (eBIC) at Diamond Light Source, UK

Lorna Malone[1], Dr Eilis Bragginton[1]
[1]eBIC, Diamond Light Source, Oxford, United Kingdom

Poster Group 2

Three-dimensional electron microscopy (3D EM) includes multiple techniques for studying large macromolecular assemblies and cellular machinery. 3D EM provides the ideal tools for discovering the structures of individual proteins and small complexes in vitro, as well as understanding their function in a larger cellular context in situ. State-of-the-art electron microscopy is often too expensive and technically demanding for individual labs to house and operate. For this reason, the Electron Bio-Imaging Centre (eBIC) was established as the UK's national centre for cryo-electron microscopy (cryoEM) following the award of a £15.6 million grant from the Wellcome Trust, the Medical Research Council (MRC) and the Biotechnology and Biological Sciences Research Council (BBSRC).

eBIC's vision and mission:
- Establish state-of-the-art facilities for cryo-electron microscopy (cryoEM) and cryo-electron tomography (cryoET)
- Provide 24/7 free user access to high-end microscopes through peer-review process
- Develop cutting-edge technology with in-house research program
- Grow and train cryo-EM user community
- Foster integrated structural biology within Diamond and beyond

eBIC is a CryoEM center providing scientists with state-of-the-art experimental equipment and expertise in the field of cryo-electron microscopy, for single particle analysis, electron tomography and electron diffraction. The location of eBIC enables scientists to combine their techniques with many of the other cutting-edge approaches that Diamond offers.

Currently eBIC houses five Titan Krios microscopes, a Talos Arctica, two Glacios, a Scios and an Aquilos cryo-FIB/SEM, and a Leica CryoCLEM.

XRD and TEM study of the quasicrystalline phase in pellets consolidated using spark plasma sintering

Dr Ruitao Li[1,2], Dr Khiam Aik Khor[3], Dr Zaoli Zhang[4], Dr Chris B Boothroyd[2], Associate Professor Zhili Dong[2]
[1]School of Mechanical Engineering, Jiangsu University, Zhenjiang, China, [2]School of Materials Science and Engineering, Nanyang Technological University, Singapore, Singapore, [3]School of Mechanical & Aerospace Engineering, Nanyang Technological University, Singapore, Singapore, [4]Erich Schmid Institute of Materials Science Austrian Academy of Sciences, Leoben, Austria

Poster Group 2

The production of quasicrystal powders by gas atomization has been commercialized. Among various quasicrystals synthesized, Al-Cr-Fe and Al-Cu-Cr-Fe quasicrystals are very promising materials for coatings and reinforcements in composites due to their high hardness, good wear and corrosion resistance and the relatively low cost of their constituent metals [1]. As these quasicrystals are metal based, the behavior of bonding between the quasicrystalline reinforcement phase and the metal matrix is superior to that for ceramic phase reinforced metal-matrix composites. However, long duration sintering can result in phase changes and decrease the beneficial properties of the quasicrystals in the composites.
In our study, we employed spark plasma sintering to shorten the heating duration for the Al-Cr-Fe and Al-Cu-Cr-Fe quasicrystal powders and thus minimize the chance of phase changes when fabricating quasicrystalline reinforced composites. The phases of the sintered compacts were analyzed using x-ray diffraction. The microstructure of the quasicrystalline phases was further studied using high resolution transmission electron microscopy.
Experimental results showed that even when the heating duration was as short as 30mins during spark plasma sintering at 650ºC, phase changes could still occur. X-ray diffraction patterns showed peaks from the decagonal Al-Cr-Fe phase while HRTEM images revealed that in decagonal Al-Cr-Fe quasiperiodic planes were periodically stacked along the 10-fold axis with a periodicity of about 1.2nm. Spark plasma sintering of icosahedral Al-Cu-Cr-Fe and pure Al blended powders was conducted at 450ºC for 10mins and no phase change was detected using X-ray diffraction or high resolution electron microscopy. This implies that spark plasma sintering is effective in fabricating quasicrystal reinforced Al-based composites.

Poster Group 1

Background and aim
Alien invasive plants are rich in specialized metabolites presenting promising potential as a valuable reservoir of bioactive phytochemicals applicable to the pharmaceutical sector. A critical requirement for their practical application is their non-toxicity. This study aims to assess the genotoxic activity of leaf and flower extracts of Ailanthus altissima (Mill.) Swingle, Robinia pseudoacacia L, Helianthus tuberosus L., and Solidago canadensis L. from Istria (Croatia) by the comet (single cell gel electrophoresis) assay.
This study is performed in the framework of the project "NATURe as an ALLY: Alien Invasive Plants as Phytopharmaceuticals— NATURALLY" (IP-2020-02-6899) and "Young Researchers' Career Development Project–Training New Doctoral Students" (DOK-2021-02-3094) founded by Croatian Science Foundation. The study aims to propose a new model for exploring new invasive alien plant species in provisioning (medicinal) ecosystem services on the pilot territory of Istria (Croatia). This study represents the first of its kind in the region since it's known that the phytochemical composition and biological characteristics of plants depend on the abiotic and biotic traits of their habitat.
Methods
Plant extracts were prepared using finely minced air-dried leaves and inflorescences collected and pooled from 15 locations in Istria and solved in 2% dimethyl sulfoxide (DMSO) in Endothelial Basal Medium-2 (EBM-2, Lonza, San Diego, CA). The ability to induce in vitro genotoxic effect in human liver-derived endothelial cells (HLEC) was assessed for three extract concentrations: 1.0 mg/ml, 0.5 mg/ml, and 0.1 mg/ml. Comet assay was stained with GelRed Nucleic Acid Gel Stain, visualized with Zeiss Axioscope 5 fluorescence microscope, and analyzed using the software KOMET5 (Kinetic Imaging Ltd., Liverpool, UK). The tail DNA percentage (% tDNA) was used as the primary measure of DNA damage.
Results
The treatments with leaf and flower extracts of all four species in concentrations of 1.0 mg/ml resulted in a significant increase of % tDNA compared to the control. Additionally, the leaf and flower extracts of A. altissima and leaf extract of R. pseudoacacia in 0.5 mg/ml also increased % tDNA.
Conclusions
These findings suggest that leaf and flower extracts in concentrations below 0.1 mg/ml do not cause substantial DNA damage in human hepatocytes, indicating a promising avenue for further research regarding the potential use of these extracts in pharmaceutical applications.

Examination of the Thermal and Morphological properties of Spartium Junceum Fibers for Flame Retardant Purposes

Zorana Kovacevic[1], Mrs. Lucia Spasevski[2], Prof.Dr. SANDRA BISCHOF[1]
[1]University of Zagreb Faculty of Textile Technology, Zagreb, Croatia, [2]Oxford Instruments NanoAnalysis, High Wycombe, United Kingdom

Poster Group 2

Fibers isolated from the Spartium junceum L. – plant which is indigenous to the Mediterranean area (SJL), belongs to a group of the plant bast fibers. Taking into the account previous research, it is proven to be an excellent fibrous raw material which, among others things, can play a role as a reinforcement in the production of fiber-reinforced composite materials. Nowadays, due to the increasing environmental awareness and the need to reduce negative impact of production by-products on climate, there is an effort to develop new materials from sustainable sources. Such materials can be functionalized through targeted ecologically acceptable surface modifications. The fire risk control is a very important concept in all branches of industry, especially in the automotive where the property of reduced flammability of the materials is very desirable. In order to meet such demands bast cellulosic fibers that are easily flammable need to be modified. In this resea3rch, SJL fibers were specifically treated with silicon dioxide, aluminum oxide and titanium dioxide nanoparticles that were fixed on the fiber surface using microwave irradiation or contact heat transfer (hot press). SiO_2 (SiNPs) and Al_2O_3 (AlNPs) nanoparticles were produced by laser ablation in liquid using a high power laser which ablates the metal plates without surfactant or aggressive chemicals addition. SJL fibers were treated with 0.025% aqueous solution of SiO_2 and Al_2O_3 nanoparticles and 2% of TiO_2 (TiNPs) nanoparticles, respectively by using ultrasound technique. Examination of the thermal and morphological properties of functionalized fibers were performed using thermogravimetric (TGA), microscale combustion calorimetry (MCC), scanning electron microscopy (SEM) & energy dispersive spectroscopy-EDS (backscatter electron and X-ray technique (BEX), X-MaxN 150 detector, ULTIM Max 100 detector and Ultim Extreme detector). For the samples fixed with the contact heat transfer heat release and thermal decomposition results are exhibit same properties as untreated sample and were therefore excluded from the further analysis. The best results were achieved by treatment with Al_2O_3 and TiO_2 nanoparticles which were fixed to fiber surface with microwave irradiation. According to the MCC analysis Heat release capacity (HRC) and Peak heat release rate (PHRR) measure the amount of the heat which is generated throughout the combustion process and the maximum rate of the heat release, respectively. In these samples, a significant reduction of the heat release rate (HRR) peak is visible (From 157 W/g for untreated to 137 W/g for AlNPs treated fiber). AlNPs treated sample show a later start of the decomposition in comparison to the untreated sample at approx. 386 °C. TGA analysis shows a residual char yield increase in all treated samples confirming their better flame retardancy in comparison to the untreated sample. Untreated fiber starts to decompose at approx. 345 °C and ends at approx. 686 °C, while thermal decomposition for fiber treated with AlNPs ends at approx. 711 °C. Considering the very small amount of deposited SiO_2 and Al_2O_3 nanoparticles and the sheer size of them on the surface of the fiber, several different mapping approaches for chemical elements determination were compared. BEX technique was proven to give best results for quick inspection of large surface area due to combination of BSE imagining and high throughput EDS sensors. While for more detailed inspection, to confirm the presence of a small concentration of nanoparticles on SJL fiber surface

Ultim Extreme was proven to be the best solution that can provide enough X-ray signal even at low voltage (3kV) and low beam current (700pA) conditions necessary to image nanoparticles.

Momentum-resolved EELS and CL investigation on 1D-plasmonic crystal fabricated by focused ion beam method

Dr. Akira Yasuhara[1], Masateru Shibata[1], Wakaba Yamamoto[1], Izzah Machfuudzoh[2], Sotatsu Yanagimoto[2], Takumi Sannomiya[2]
[1]JEOL Ltd., Akishima, Japan, [2]Tokyo Institute of Technology, Yokohama, Japan

PS-11, Lecture Theater 2, august 28, 2024, 14:00 - 16:00

Background and aims;
Plasmonic crystals with periodic structures constructed from plasmonic materials have been widely investigated, as they exhibit attractive optical properties based on surface plasmon polaritons (SPPs). To explore the optical properties of plasmonic crystals at the nanoscales, electron energy loss spectroscopy (EELS) and cathodoluminescence (CL) techniques based on scanning transmission electron microscopy (STEM) are the two complimentary approaches; EELS gives the information on the excitation process and thus allows accessing the optical information outside the light line while CL gives information of the photon emission meaning the information inside the light line. With the angle-dependent detection, momentum-resolved spectra, i.e. dispersion relations, can be obtained by both techniques. In this study, we fabricated a one-dimensional plasmonic crystal (1D-PIC) from Al using a focused ion beam (FIB) method and thoroughly investigate their optical properties using momentum-resolved EELS and CL methods.
Methods;
1D-PIC was fabricated using a JIB-PS500i instrument (FIB-SEM system) with a focused Ga-ion beam. At first, an Al thin lamella consisting of large grains(> um) was prepared out of bulk Al to ensure the sufficient propagation of SPPs. The periodic structure was then carved with a precise control of the ion beam dose to create the terrace and trench structures using the specimen drift compensation function to prevent structural sagging. To analyze the optical properties, a JEM-ARM200F(TEM/STEM) instrument with GIF Continuum ER was used for the momentum-resolved EELS, and a modified JEM-2100F(TEM/STEM) instrument with a dedicated CL measurement system was used for the momentum-resolved CL.
Results;
Figure 1a shows TEM BF image of Al 1D-PIC, confirming the successful fabrication of the periodic structure of 500 nm periodicity with the terraces and trenches of the same width. Panels b and c in Fig.1 show the momentum-resolved EELS and CL spectra of Al 1D-PIC, where the dispersion relations of SPs are clearly visualized. The superimposed curves in panels b and c display the calculated dispersion of Al SPPs. The light lines are also indicated on images by yellow dotted lines. It is noted that EELS has the capability of accessing the information outside of light line, while the CL technique can investigate only the photon information inside of the light line. On the other hand, the CL technique has a strong advantage to achieve both nanoscopic spatial resolution and momentum resolution by utilizing the electron beam for the spatial resolution and photon detection for the momentum detection. The employed CL equipment allows acquiring the momentum-resolved CL spectrum at each electron beam position while scanning the electron beam, thus producing four-dimensional (4D) CL data set. In the EELS result, shown in Fig. 1b, enhanced horizontal lines along the momentum axis with 2.6, 5.0, and 6.5 eV are visible, which can be assigned as the localized surface plasmon modes. These local modes can be understood from the resonance conditions where the SPPs make standing waves with different orders matching the local structure of 1D PIC. The momentum-resolved CL results, as shown in Fig. 1 c, display the dispersion relation reproduced from

the upward photon emission from the specimen. Since the periodic structure is constructed on the top surface of the specimen, dispersion lines are clearly visible only in the upward emission. In addition to the dispersion line depicted in Figure c, discernible local mode around 2.6 eV, extending the intensity in the momentum direction, is also evident.

Conclusion;

We have successfully fabricated the 1D-PIC using the FIB technique out of large grains of Al. The presence of SPP and local modes on the 1D-PIC were confirmed using the EELS and CL techniques. Furthermore, through the momentum-resolved EELS and CL mapping analysis, we identified the dispersion relations of SPPs and local modes. Through the combination of momentum-resolved EELS and CL measurements, comprehensive investigations can be performed, which allows accessing the optical properties of nanostructures far beyond the diffraction limit of light.

Figure caption;

Figure.1 (a) TEM BF image of the Al 1D-PIC fabricated by the FIB method. A schematic illustration of the structure is shown in the inset. (b) Momentum-resolved EELS result. The dashed circles indicate the diffraction spot positions reflecting the period of the 1D PIC. The backgrounds of EELS signals are subtracted from the original data. (c) Momentum-resolved CL spectrum acquired in the upward direction (structured side). The CL spectrum is obtained by spatially integrating the CL signal over the 1D plasmonic crystal.

Analyses of Observed Speciation of Cobalt in NMC cathodes Using Laboratory X-ray Absorption Spectroscopy (XAS)

Andreas Bergner[1], Simon John[1]
[1]Quantum Design GmbH, Pfungstadt, Germany

Poster Group 1

We report the X-ray Absorption Spectroscopy (XAS) investigation of four samples of NMC electrodes using QuantumLeap™ H2000. Co XANES show three isosbestic points. Principal component analysis (PCA) and Iterative Target Transform Factor Analysis (ITTFA) reconstruction of the experimental X-ray Absorption Near Edge Structure (XANES) show that two of the samples contain two unique species of Co. In the remaining samples, the speciation of Co can be described by the linear combinations of the two distinct species, validating QuantumLeap's synchrotron-like performance.

Observing Lithium Ion Battery Bonds During Charge Cycling Using Laboratory XAS

Andreas Bergner[1], Simon John[1]
[1]Quantum Design GmbH, Pfungstadt, Germany

Poster Group 1

X-Ray Absorption Spectroscopy (XAS) analyses of measurement results obtained with QuantumLeap H2000 of Lithium ion NMC batteries are presented. For the set of samples analyzed, Mn is largely electrochemically inactive and the octahedral coordination is retained. The Mn-O and Co-O bond lengths are shown to change minimally with cycling whereas the Ni-O bond suffers from Jahn-Teller distortion.

In situ microscopic observations of zinc electrodeposition process in various electrolytes

Dr Kaname Yoshida[1], Dr. Yuki Sasaki[1], Dr. Akihide Kuwabara[1], Prof. Yuichi Ikuhara[1,2]
[1]Japan Fine Ceramics Center, Nagoya, Japan, [2]The University of Tokyo, Bunkyo-ku, Japan
PS-04 (1), Plenary, august 26, 2024, 10:30 - 12:30

-Background and Aims-
Zinc anode batteries are expected as low-cost and high energy density batteries. While they have already been widely utilized as primary batteries, there are many problems in the application to a secondary battery [1]. In particular, the dendrite formation during the charging process is a major issue for development of rechargeable zinc anode batteries. Dendrite growth from the zinc anode is known to cause internal short-circuiting between the cathode and the anode. In order to suppress dendrite formation effectively, it is important to clarify the formation mechanism. However, electrochemical reactions in the liquid electrolytes involve many factors and they proceed through complex mechanisms. Clarifying ever-changing electrochemical reactions at the electrode (solid) – electrolyte (liquid) interface, in situ microscopic observations are advantageous. Because of such requests, we had started in situ observations of zinc electrodeposition process by using liquid-phase transmission microscope (LP-TEM). As a result, we succeeded in observing the dendrite formation at the early stage of zinc electrodeposition process [2]. However, in situ electrochemical observations with LP-TEM suffered from the problem of low reproducibility due to the severe limitation in liquid thickness. The condition of a liquid electrolyte surrounding a working electrode for LP-TEM can be changed drastically as the redox reaction proceeds. Furthermore, it was difficult for the LP-TEM method to handle a wide range of electrolytes, due to the restrictions on liquid properties.
Therefore, we devised noble setup of liquid-phase scanning electron microscope (LP-SEM) for in situ observations of electrochemical reaction in various liquid electrolytes [3]. Our LP-SEM setup for electrochemical reactions enables in situ observations in bulky liquid electrolytes and is expected to improve the reliability of reactions.
-Methods-
In situ electrochemical TEM (EC-TEM) observations of zinc electrodeposition in were carried out by combining the TEM (TITAN E-TEM, Thermo Fisher Scientific) and the liquid-cell holder (Poseidon Select, Protochips) under the accelerating voltage of 300 kV.
In situ electrochemical SEM (EC-SEM) was constructed based on atmospheric SEM (JASM-6200, JEOL). A noble electrochemical reaction vessel was created by using a commercially available electrochemical chip for LP-TEM (ECT-15WO, Protochips). Electrochemical reactions were controlled by an external potentio/galvanostat (SP-300, Bio-Logic Science Instruments) through the working electrode (WE) on the chip, metal wires as a counter electrode (CE) and a quasi-reference electrode (RE). Overview of our EC-SEM equipment shown in the figure.
-Results and Conclusions-
First, reliability of our EC-SEM setup was confirmed in a zinc electrodeposition reaction under similar conditions with EC-TEM observations. Compared with EC-TEM observations, reproducibility of zinc deposition processes and their electrochemical conditions were drastically improved. That is, EC-SEM observations can make it possible to reveal the correlation between electrochemical conditions and deposited zinc shape.
Next, zinc deposition processes in several kinds of electrolytes under different electrochemical conditions were compared by using EC-SEM observations. In comparing various constant current

conditions, shape changes of deposited zinc depending on the current density were observed in EC-SEM. For example, in a 0.5 M zinc sulfate solution, a dendric zinc structure was formed at a current density of > 2 A/cm². The shape of the deposited zinc was found to depend not only on the electrochemical conditions but also on the kind of counter anion and the concentration of zinc cation in liquid electrolytes. The details about the relationship between reaction conditions and deposited zinc shapes will be discussed.

LS-08, Lecture Theater 4, august 28, 2024, 10:30 - 11:30

Background incl. aims.
Mycoplasma pneumoniae is a genome-reduced pathogenic bacterium that is the causative agent of a number of respiratory diseases and an established prokaryotic minimal cell model. While the drastic gnome reduction that Mycoplamsa pneumoniae underwent results in only about 500 proteins being expressed, approximately 20% of its genes remain completely uncharacterized. Here, I present our developed approaches aimed at advancing functional identification of previously uncharacterized proteins by in-cell structural biology.

Methods.
Mycoplasma pneumoniae was grown on cryo electron microscopy grids, frozen in vitrious ice, and tilt series was collected on the electron microscope. Particles were first segmented manually in the tomograms, where after deep neural network models were trained to further pick particles. The final cryo electron tomography map was generated by subtomogram averaging. Structures of potential candidates for the proteins were predicted using AlphaFold and rigid body refined against the map. Further proteins were identified using proteomics including, surface shaving mass spectrometry and in-cell cross-linking mass spectrometry. Structural and sequence homology searches were performed to identify functional domains in the uncharacterized proteins.

Results.
The small size of Mycoplasma pneumoniae allowed us to collect over 600, high-resolution cryo-electron tomography datasets without thinning the sample, thereby setting the stage for visual proteomics of an entire cell. In the resultant tomograms, we observed an abundant integral membrane protein complex with a large extracellular dome-like structure. We resolved the protein complex to sub-nanometer resolution by subtomogram averaging. To identify the components constituting the complex, we generated a candidate list of cell surface proteins by enzymatic surface shaving coupled to mass spectrometry, and predicted their structures using AlphaFold. The predicted structures were systematically fitted into the subtomogram averaged map, enabling us to identify three homologous lipoproteins constituting the major part of the extracellular dome. Whole-cell cross-linking mass spectrometry revealed that the three proteins form a hetero-trimeric complex. The cross-linking data also showed that an additional lipoprotein, as well as the integral membrane protein SecDF, are also present in the complex. SecDF is required for efficient translocation by the Sec translocation machinery in other bacteria. Fitting the AlphaFold models of the Sec translocon proteins secA and secYEG into the STA showed that the remaining Sec components are also present in the dome-like structure, and provide a first structural model of the conserved bacterial

translocation machinery. The three homologous extracellular lipoproteins are uncharacterized, with yet unknown functions, but are all essential for Mycoplasma pneumoniae. Structural homology searches revealed that the extracellular proteins contain a prolyl isomerase domain found in periplasmic and extracellular chaperones in other bacteria. Furthermore, only one of the three proteins retains the conserved residues important for substrate binding and catalysis. This is also the component that exhibits a prominent contact with a heterogenous substrate density observed inside the extracellular dome. Classification of the particles showed that a sub-population of the complex interacts with the membrane-associated ribosomes. The fraction of ribosome associated complexes increased when Mp was exposed to antibiotics which halt protein production, indicating stabilization of an otherwise transient interaction. In the antibiotics-treated cells, we also observed a more open conformation of the complex corresponding to the resting state where no translocation occurs. This allowed us to describe the conformational changes that take place upon translocation, especially in secDF.

Conclusions.
Our data suggest that we have discovered a non-canonical sec-translocation complex involved in protein translocation and folding in Mycoplasma pneumoniae, and demonstrates how in cell cryo ET can contribute to de novo structure determination and functional assignment of previously uncharacterized proteins.

Poster Group 1

The Fe-Cr-O ternary system has been studied extensively since the mid-20th century due to its applications in various fields, such as geology, metallurgy, corrosion, and (more recently) spintronics. In this system, solid oxide phases may appear in three different crystallographic structures: the halite, the corundum and the spinel phases. The spinel structure (Fe3-xCrxO4) is a mix of divalent and trivalent cations in the cubic MgAl2O4-type structure. Multivalence cations are organized in a geometrically frustrated network of octahedral and tetrahedral sites, termed here Oh-sites and Td-sites respectively.The complexity of the spinel structure opens the way for tailoring the functional properties of these materials (magnetization, Curie temperature, electronic transport by incorporating different metal cations into the host matrix. For instance, substitution of Fe cations for Cr in magnetite converts the half-metal host ferrimagnet into either a semiconductor or an insulator, depending on the x values.
Most previous works on the Fe3-xCrxO4 series are based on bulk-like samples, while thin films have received limited consideration. Numerous studies have shown that physical and chemical properties of thin films strongly deviate from the bulk, depending on the growth method, film thickness, and surface and interface effects.
This work presents a comprehensive study of the influence of composition and structural properties of epitaxial Fe-Cr-O thin films.

Thin films were deposited by oxygen-plasma-assisted molecular beam epitaxy (O-MBE) on single crystalline α-Al2O3(0001) substrates. This method was chosen as it enables the synthesis with a perfect control of the chromium content (x) by using individual Knudsen effusion cells under a reactive atomic oxygen plasma. During deposition, reflection high-energy electron diffraction (RHEED) patterns were acquired in real time to control the crystalline structure of the oxide formed. Epitaxial growth of 15nm thick Fe3-xCrxO4(1 1 1) thin films of high crystalline quality has been obtained.
Following growth, several characterization techniques were used to obtain chemical and structural information from the thin films. The stoichiometry of the Fe3-xCrxO4 films were verified ex situ by X-ray photoemission spectroscopy (XPS) measurements. The film microstructure was investigated via high-resolution transmission electron microscopy (HRTEM) and complementary quantitative elemental analyses were performed by electron energy loss spectroscopy (EELS) and energy-dispersive X-ray spectroscopy (EDX). X-ray absorption near-edge structure (XANES) and extended X-ray absorption fine structure (EXAFS) measurements were carried out on MARS Beamline of synchrotron SOLEIL to resolve the oxidation state and the first cation-neighbors bond distances. Magnetic hysteresis loops and in-plane electrical measurements were conducted. The Cr and Fe cation site distribution was determined by exploring the L2,3-edge X-ray absorption (XAS) and

circular dichroism (XMCD) measurements performed on DEIMOS Beamline of synchrotron SOLEIL. Multiplet calculations were used to interpret the dichroism signal.
Stoichiometric series of epitaxial Fe3-xCrxO4(111) thin films were prepared with x varying from 0 to 1.7. The film stoichiometry was first evaluated ex situ by XPS measurements. Since XPS probes only the surface, complementary chemical analyses were performed by STEM-EELS and STEM-EDX. Those analytical techniques presented similar trends with minimal fluctuations in the Fe and Cr signals throughout the layers and no composition gradient.
For x < 1.4, RHEED patterns exhibit sharp streaks and no spots, indicating a bidimensional growth mode and layers of high crystalline quality without secondary phases. However, for x > 1.4, RHEED images are blurred and the streaks are almost indistinguishable. The layer-substrate interface and structural defects were evaluated by cross-sectional transmission electron microscopy (TEM) images. Figure 1 (left) depicts TEM images of a representative Fe2.8Cr0.2O4 film studied along the [1210] direction. Low magnification TEM image shows that the film is homogeneous and has a constant thickness of about 15 nm. A perfectly flat and abrupt Fe2.8Cr0.2O4/Al2O3 interface is observed with no noticeable parasite phases at atomic scale. Misfit dislocations, which takes part on the relaxation mechanism of these films, are observed, as already mentioned for other ferrites grown on sapphire substrate by O-MBE (e.g. NiFe2O4 and MnFe2O4). When comparing HRTEM images of Fe2.8Cr0.2O4 and Fe2.3Cr0.7O4 films, the increasing Cr content seems to induce disorder in the crystalline structure of the film and many stacking defects (e.g., APBs and dislocations) are observed. To investigate further this issue, HRTEM images were acquired for Fe1.6Cr1.4O4 (figure 1 right) and buffer-Fe1.3Cr1.7O4. The increase in the amount of the crystalline nanodomains is unmistakable for both of these layers compared to the first two compositions. These results corroborate well with the decrease in quality of RHEED images. The influence of Cr content on the crystalline quality of the films can be associated to either changes in the cation distribution among tetrahedral and octahedral sublattices or modifications in the growth conditions as the deposition rate is different. For x < 0.5 the replacement of Fe3+ by slightly smaller Cr3+ in Oh-sites does not modify drastically the structure, whereas for 0.6 < x < 1.3 the displacement of larger Fe2+ into Td-sites has a huge influence. Indeed, orbitally active Fe2+ cations in Td-sites lead to tetragonal distortions due to cooperative Jahn-Teller effects. For compositions with x > 1.4, films are assumed to have the normal type of spinel structure, Fe3+ cations are replaced by smaller Cr3+ in Oh-sites.
In addition to changing the structural quality, cation disorder has a major impact on the physical properties of the films. The total magnetization and the magnetic anisotropy of Fe3-xCrxO4 thin films decrease as the x values increase. But unlike bulk materials, thin films with high Cr content (x ≥ 1.2) still show magnetization at room temperature, i.e., near (or above) the Curie temperature of bulk samples. These features were interpreted in the light of the cationic site distribution. For both bulk and thin films, the inversion parameter steadily evolves with composition, ranging from an inverse arrangement (Fe3O4) to normal ordering (FeCr2O4). Because Cr-rich thin films are still intermediate spinels, while bulk samples are normal spinels, the Curie temperature of these films were increased as they present stronger Td-Oh antiferromagnetic interactions. These results confirm that doping magnetite thin films with Cr is very effective to control the magnetic behavior of this material.

Electron and x-ray spectroscopy for real-space electronic structure mapping in superconducting nickelates

Berit Goodge[1]
[1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

IM-05 (1), Lecture Theater 3, august 26, 2024, 10:30 - 12:30

Background and aims: The recently discovered superconducting nickelates are an archetypal example of how exotic or functional properties can be realized by careful materials synthesis and engineering. While many fundamental aspects of these materials remain under active investigation, it is clear that (as with many quantum materials) they are rooted in strong interactions between atomic structure, orbitals, and electronic charge. The unique sample geometry and complicated synthesis of the so-called infinite-layer nickelates, however, have not only raised questions about the origin of superconductivity in thin film specimens and generally hindered the use of many common “field-standard” spectroscopic probes. Here, I will focus on two advanced core-level spectroscopic techniques, both of which provide unique access to real-space electronic information.
Methods: At the atomic scale, highly local spectroscopic measurements are conducted by electron energy loss spectroscopy (EELS) in the scanning transmission electron microscope (STEM) with a sub-Ångström probe to enable location-specific measurements across the doping-dependent superconducting dome in nickelate thin films. Leveraging hard x-rays at high-brilliance synchrotron facilities, we harness beyond-dipole and dipole-forbidden transitions with s-orbital non-resonant inelastic x-ray scattering (sNIXS) to directly map the complete charge density [1] in bulk undoped infinite-layer nickelates.
Results: Area-selective STEM-EELS measurements reveal a distinct electronic landscape in the superconducting nickelate, particularly in regards to nickel hybridization, and it’s doping evolution across the superconducting dome which point to multi-band superconductivity [2]. Elemental and electronic investigation across the atomic substrate-film interface provide definitive evidence against the picture of possible interfacial superconductivity hosted at a strongly polar oxide interface [3]. The quantitative precision offered by bulk sNIXS measurements are used to investigate questions of nickelate “self-doping” in chemically undoped compounds through strong interactions with rare-earth states.
Conclusions: The insights offered by hyperspectral techniques, particularly those with real-space sensitivity, are crucial for building fundamental understanding of many quantum, biological, and functional materials. Both techniques described here can be further extended to in situ or operando conditions, opening the door to study phase evolution driven by temperature, pressure, fields, etc., some challenges and promising developments of which I will also mention [4,5].

An advanced smart counting mode for pixelated direct electron detectors based on semiconductors

Dr. Björn Eckert[1], Mr. Stefan Aschauer[1], Mr. Martin Huth[1], Mrs. Petra Majewski[1], Mrs. Heike Soltau[1], Mr. Lothar Strüder[2]
[1]PNDetector, München, Germany, [2]PNSensor, München, Germany, [3]University of Siegen, Siegen, Germany

Poster Group 2

Pixelated direct electron detectors identify electrons by their interaction with the sensitive detector volume. The relevant interaction is an energy deposition via electron-electron scattering. However, in applications like 4D-STEM, the user is interested in the spatial-resolved absolute number of incident electrons on the detector surface. Therefore, the goal is to count each electron exactly one time at the position it crosses the detector surface. The following assumptions were made for silicon as detector material but are transferable to other materials as well.
Low-energetic electrons (E ≈ 10 - 30keV), as used in scanning electron microscopes, typically deposit their energy in a small volume very close to the point of entry. This volume is mostly much smaller than the size of the pixel structure (e.g. for the standard pnCCD 48 µm x 48 µm).
High-energy electrons with energies > 100 keV, as usually used for transmission electron microscopes, typically do not deposit their energy locally at one specific point but deposit the energy in many steps along three-dimensional tracks through the detector volume. For electrons with a primary energy of 300 keV, the average length of these tracks is 450 µm. The shape of these tracks is caused by multiple scattering of the electrons in the detector volume and, therefore, is stochastic.
The energy deposition in the three-dimensional detector volume locally generates charge carriers that form a charge cloud. Direct electron detectors like the pnCCD collect the charge cloud at the opposite side of the entrance window. Therefore, the charge cloud drifts due to an applied electric field to the opposite side of the detector. During the drift time, the size of the charge cloud increases due to repulsion of the charge carriers themselves and due to diffusion. In comparison to the statistical behavior of the energy deposition, the drift process behaves deterministically. The collected charge carriers in each pixel of the pixel structure correspond to the binned two-dimensional projection of energy deposition, widened by the drift process. The total number of charge carriers is directly related to the amount of deposited energy.
For low primary energy, the structure of the charge cloud is mostly just influenced by the primary energy of the electron itself, and its point of entry relative to the pixel structure. Therefore, for electrons that enter the detector at the same point with the same primary energy the pixel-wise collected charge clouds look similar. For higher energetic electrons, the size and the shape of the pixelated charge cloud are mostly influenced by multiple scattering. Therefore, the distribution of the pixel-wise collected charge carriers is different for each individual electron. During the detector readout, the pixel-wise collected charge carriers are transferred into a detector response. If the measuring process of the number of individual charge carriers in each pixel is sufficiently precise, the detector response is a good approximation of the two-dimensional projection of the charge cloud. The structure of the 2D projection can be used to calculate the point of entry for individual electrons for higher energetic electrons on pixel level and for lower primary energies even on sub-pixel level. However, for some applications in TEMs and SEMs require a higher electron flux on the detector such that the measured two-dimensional projection of the charge clouds of two or multiple primary electrons overlap. This leads to three different regimes depending on the flux. The first regime is

where the detector response of individual electrons is separable. The second regime has contributions where multiple electron traces overlap but the contributions of the individual primary electrons are still visible. The third regime is dominated by a very high flux that leads to intensity images. In the third regime, the contributions of individual primary electrons are not visible anymore. Different regions in the same diffraction pattern can hold different regimes.
Our algorithm can handle the different regimes in flux on pixel level and reconstructs the number of contributing primary electrons and their points of entry. The point of entry reconstruction happens depending on the energy of the primary electrons and the flux on physical pixel level or subpixel level in real-time. In this contribution, we will show that the proposed Smart Counting algorithm significantly increases the precision in counting the number of primary electrons and their spatial position compared to a simple counting mechanism by individual discriminators on pixel level.

Manipulating topological magnetic structures by in-situ Lorentz microscopy

Dongsheng Song[1]
[1]Institutes of Physical Science and Information Technology, Anhui University, Hefei 230601, China, Hefei, China

Poster Group 1

Topological magnetic structures, i.e., skyrmions, have been considered as promising carriers in future magnetic storages or logical devices since their discovery in chiral magnets from 2009, owing to their nanometer-sized dimension, high stability and low critical current density of manipulation. The topologically protected spin textures are fundamental to these excellent performance metrics over the conventional magnetic domain walls or nanoparticles. Here, we have utilized the state-of-the-art magnetic imagining techniques, i.e., Lorentz microscopy and off-axis electron holography, to visualize the magnetization or emergent field of topological magnetic objects, in order to clarify the underlying mechanism of stability and evolution. Moreover, in-situ electrical Lorentz microscopy is employed to investigate the current-driven dynamics of skyrmions in nanostructures under the nanosecond current pulses. The skyrmion velocity and skyrmion Hall angle are measured with respect to the current density. Our results prove the possibility of coding the skyrmions in prototypical devices and have immediate significance towards the skyrmion-based memory or logic devices.

The HeXI project, funded by the Wellcome Trust “Electrifying Life Sciences” grant and Diamond Light Source, aims to build a dedicated electron diffractometer to investigate the potential of Mega-electron volt (MeV) electrons for the determination of molecular structures from nanometre sized crystals. The HeXI instrument will leverage the increased penetration of MeV electrons and the high precision goniometry, cryo-sample transfer systems and sample preparation methods developed at Diamond to target crystal thicknesses between 300 nm and ~1 µm to determine the molecular structures of proteins and pharmacologically relevant molecules. The ability to acquire high-fidelity sweep and serial diffraction data from ≤1-micron thick crystals will bridge the current crystal size gap between samples amenable to electron diffraction performed on commercial Transmission Electron Microscopes (TEMs) using <300 nm crystals and microfocus X-ray diffraction of >3 µm crystals at microfocus beamlines

Poster Group 1

Background and aims
Hydrogen fuel cells are an important technology for decarbonising road transport and shipping. Their efficiency is limited by the oxygen reduction reaction (ORR), which requires catalysts to achieve acceptable performance for the cell. The state of the art ORR catalysts are Pt-X nanoparticles, where X is another transition metal. These nanoparticles have a core-shell structure, consisting of an alloyed Pt-X core surrounded by a Pt rich shell. They perform much better as ORR catalysts than pure Pt nanoparticles, however the origins of this activity enhancement are not fully understood. The main factors that are hypothesised to be responsible are ligand effects, where chemical differences between Pt and X modify the electronic properties of the catalyst surface, and strain effects, where changes in nanoparticle size and shape induced by the size mismatch between Pt and X lead to changes in electronic structure. Core-shell nanoparticles have been observed to have a high degree of strain at the surface which affects the d band structure at the nanoparticle surface, which is crucial in determining O binding strength and ORR catalytic activity. Complex strain states with a significant shear component have been observed in the outer layers of core-shell nanoparticles via atomic resolution scanning transmission electron microscopy (STEM); while the effect of volume changing normal strains on catalytic activity has been widely studied, those of shape changing shear strains have been largely overlooked in the literature. Our key aim in this work is to use computational modelling to understand the electronic properties of experimentally observed nanoparticle structures, and the effect of these properties on catalytic activity, as a step towards better understanding the structure-property relationship and improving fuel cell catalyst design.

Methods
Microscopy: Alloyed Pt-Co core-shell fuel cell catalyst nanoparticles on C have been provided by Johnson Matthey. Atomic resolution high angle annular dark field STEM (HAADF-STEM) with EDX and EELS has been performed on these nanoparticles to understand their structure and composition at the atomic level. Column positions relative to a reference grid which is fitted to a nanoparticle structure have been used to measure variations in strain across its extent. The compositional information allows the elastic strain to be distinguished from lattice parameter changes arising from different local alloy compositions.

Computation: DFT calculations have been performed using CASTEP 22.11 on pure Pt to measure the effect of normal and shear strains on the d band centre. All calculations were performed with the PBE functional. Equilibrium bulk and slab structures were first obtained by geometry optimisation. Strain states representative of those seen in STEM images of catalyst nanoparticles were then applied and the d projected PDOS and d band centre of these strained structures were calculated and compared.

Results

Atomic resolution HAADF-STEM measurements of catalyst nanoparticles have shown that the outer layers exhibit both normal and shear strains relative to the reference structure that was fitted to the nanoparticle. DFT calculations have shown that the shear strains typically observed in catalyst nanoparticles are unlikely to have a significant effect on their electronic properties.

Conclusions
The ability to reliably map strain at the atomic scale for nanoparticles is an important step in linking structure to activity, and ultimately determining the optimal surface structure for ORR catalysts. The independence of electronic properties on small shear strains suggests that unit cell volume is a key descriptor of catalytic activity.

Volume Electron Microscopy (vEM) provides high-resolution data of target structures and resolves three-dimensional representations of otherwise ambiguous biological geometries. While EM provides high spatial resolution, search processes in volumes of several hundreds of square microns is tedious. Multimodal methods like correlated light and electron microscopy (CLEM) allow to bridge these scales. Among the available vEM techniques, array tomography methods like automated tape collecting ultramicrotomy (ATUM) have proven particularly powerful for targeting specific or rare biological structures as needed for correlation as they enable repetitive and large field of view imaging. Previously, we have applied diverse ATUM-CLEM approaches to reveal ultrastructural correlates of neurodegenerative pathologies. These classic correlation techniques annotate ultrastructural data with one or a few molecular targets. With the advent of spatial transcriptomics (ST), the localization of cells with specific expression profiles covering several thousands of transcripts has become accessible. So far, diverging sample preparation techniques have hindered correlated ultrastructural investigation. Here, we developed STcEM, a method that links spatially-resolved gene expression of single cells with their ultrastructural morphology by integrating ST and ATUM on adjacent tissue sections. With this method we successfully mapped microglial classes according to their transcription profile and ultrastructural morphology in a mouse model of white matter lesion. Our results offer a comprehensive view of the spatial, ultrastructural, and transcriptional reorganization of single cells after brain injury.

Poster Group 2

Background incl. aims
When devices, such as transistors, are under electrical load, the resistivity of the device often leads to unwanted heat generation. In many cases, this reduces the efficiency of the device and hence is detrimental both economically and environmentally due to excessive energy consumption. However, as devices approach the atomic scale, this wasted heat generation can lead to device failure. To overcome this, materials which have excellent electrical conductivity, but poor thermal conductivity are being investigated for their potential use in devices.
One such thermoelectric material which has potential use in optoelectronics is the layered ternary chalcogenide semiconductor $TlGaSe_2$. It has been shown to have a thermoelectric figure of merit, ZT, of approximately 0.8 [1], comparable with other heavily studied thermoelectric materials such as Bi_2Te_3 [2]. However, the material's layered nature means it is prone to stacking faults, which are often assumed to affect this value [1, 3], but to date, this has yet to be established. This is critical to understand if the material is to be used in future devices, such as near-IR sensors.
Methods
In this work, $TlGaSe_2$ is characterised via (scanning) transmission electron microscopy (STEM) and density functional theory (DFT) simulations. Streaking in selected area electron diffraction (SAED) patterns are correlated to simulations which indicate the presence of stacking faults in the growth direction [4].
Results
High resolution STEM confirms these stacking faults and indicates a lack of long-range order to the stacking. DFT calculations reveals a high preference for the system to include these faults. Electron transport simulations for structure in both stacking orders show a significant enhancement of thermoelectric power along the stacking direction when stacking faults are induced. These are further enhanced if the material is doped sufficiently. Phonon dispersion calculations show a suppression of several phonons modes when stacking faults are induced, indicating a suppression of thermal conductivity.
Conclusions
Stacking faults in $TlGaSe_2$ are shown to be prevalent throughout the material and they enhance its excellent thermoelectric properties.

IM-10 (1), Lecture Theater 3, august 29, 2024, 10:30 - 12:30

Background incl. aims
Scanning transmission electron microscopy (STEM) is commonly used to estimate the particle size distribution in heterogeneous catalysts. A problem with the conventional approach of manually measuring particle diameters in STEM images is that it is labor-intensive and disregards the actual particle structure, making particle size prediction with atomic precision impossible. To overcome these limitations, we propose a machine learning approach based on the CycleGAN architecture. The model learns to map between simulated and experimental images, and a subsequent network is trained to estimate the size of an imaged nanoparticle in terms of number of atoms. This technique is fully automatic and could form the basis for a modern characterization method when combined with automated data acquisition. As catalysts should ideally be studied under reaction conditions, we also explore the possibility of extending this workflow to gas-cell measurements.

Methods
Triggered by our recent experimental results, we have developed a structure generator which can generate realistic but random atomic models of Pt nanoparticles supported on ceria. These models have been used to generate a dataset of 3500 HAADF STEM multislice image simulations. A second dataset of high resolution HAADF STEM images of Pt nanoparticles supported on ceria was recorded on a probe-corrected Titan Themis operated at 300 keV. All experimental images were recorded under identical conditions. Images in both datasets are 128x128 with a pixel size in the range 10-50 pm. The simulated and experimental dataset were used to train a CycleGAN to map between the two sets. We use 2 U-Net generators and 2 PatchGAN discriminators for the CycleGAN. With the trained CycleGAN, we then send the simulated dataset through the "simulation-to-experimental" generator, thus obtaining a new dataset of 3500 fake experimental images with a corresponding particle size ground truth. Another U-Net with a fully connected layer at the end to output a scalar size prediction was then trained on the fake experimental dataset. The trained size-estimator was applied to the experimental dataset and the particle size distribution was compared with that of the manual technique of measuring the particle diameters and assuming a hemispherical particle shape.

Results
We have successfully trained a cycle-consistent generative adversarial network to map between physical image simulations and experimental HR-STEM images of small Pt nanoparticles supported on cerium dioxide. Passing raw multislice simulated images through the network yields realistic-looking experimental images with noise profile matching that of the real experimental dataset. In the same way, passing an experimental image through the network can be compared to applying a potent denoising algorithm to the image.

We apply our size estimation network to a set of 118 experimentally observed nanoparticles in a Pt/CeO2 catalyst to get the particle size distribution. Most predictions are reasonable and the particle size distribution obtained by the size-estimator network follows that of the manual hemisphere estimation technique. We find that the mean Pt particle size in the catalyst is 117 atoms with our technique, and 154 with the hemisphere estimation technique. Typical fail-cases of our model includes images of particles larger than 500 atoms and particles oriented along a major zone axis. This is likely due to a lack of large particles in the simulated data, as well as a lack of particles in zone axis in the experimental set. This could be addressed by generating more data.

Conclusion
In conclusion, our machine learning approach establishes a connection between physical image simulations and experimental images, making it possible to train supervised machine learning techniques on realistic-looking data with a known atomic model ground truth. We have showcased this by developing a size-estimation network which proves to output reasonable size estimates when applied to experimental images. Combined with automated data acquisition, we envision techniques like this will lead to more comprehensive and accurate characterization of nanoparticle-based heterogeneous catalysts.

PS-02 (3), Lecture Theater 4, august 30, 2024, 14:00 - 16:00

Background incl. aims:
Research on phase separation in metallic glasses (MGs) is motivated by a fundamental interest in the structure and properties of disordered materials and their potential for structural and functional applications. The structure and physical properties of phase separated MGs have characteristics different from those of other MGs. Recent reports have demonstrated successful achievements in the preparation of phase-separated MGs, which offer a unique opportunity to design composites or alloys with hierarchical microstructures at different length scales. The presence of a miscibility gap between the two major elements causes the formation of two-phase glassy alloys. Phase separation can occur due to the complex interplay of negative and positive enthalpies of mixing. Efforts have been undertaken to understand the origin of phase separation in MGs through mechanisms such as nucleation and growth, spinodal decomposition, yet the understanding of the mechanism is insufficient. Phase separation reported in Ce-Al (Ga) MGs is due to changes in the electronic structure of Ce-atoms. Phase separation with nano-amorphous domains plays an important role in improving the plastic behaviour of MGs and ideally suited for small mechanically challenging applications such as dental implants because of their remarkable mechanical properties. In this presentation, we will discuss the results of our recent research work on the design of new Zr-based MG composition with nanoscale phase separation for future biocompatible applications.
Methods:
Zr-based alloy ingots were prepared by arc melting under a Ti-gettered argon atmosphere. Ribbons were created by induction melting of alloys in a quartz tube and ejected onto a copper roller at a tangential velocity of 30.6 m/s under argon atmosphere. The resulting ribbons were approximately ~4 mm wide and ~40 µm thick. The structure of the melt-spun ribbons was studied by X-ray diffraction (XRD: D2 phaser-Bruker) using Co Kα radiation. Differential scanning calorimetry (DSC) measurements were done using a Netzsch DSC 404F1 Pegasus device at a heating rate of 20 K/min. Microstructural studies were carried out using a transmission electron microscope (TEM; JEOL 2100F FEG and JEOL 220FS) operated at 200 kV. APT measurements were carried out on a LEAP5000 XR (Cameca Inc., USA). Data reconstruction and analysis were conducted with APSuite 6.3 (Cameca Inc., USA) based on the voltage curve with an initial tip radius of 55 nm.
Results:
The presence of broad diffraction maxima in the XRD profiles confirms the glassy structure of the alloys. The interpretation of the DSC data suggests that the additional exothermic peak results from the presence of two distinct co-existing glasses formed through phase separation. The microstructure and thermal property analysis indicate that the glasses exhibit a typical liquid phase separation-induced two-glassy phase with droplet-like microstructures in the form of nano-amorphous domains. The microstructure of phase separated nano-amorphous domains has been confirmed by sophisticated experimental characterization techniques including transmission electron microscopy (TEM) and atom probe tomography (APT). The presence of two distinct glassy phases with distinct

contrasts has been observed in the TEM images. There is a matrix in which another phase is dispersed. The selected area diffraction (SAD) patterns displays two diffuse halos from the matrix and the dispersed phase. The formation of extremely fine nano-amorphous domains of 10 nm size can be seen in the TEM micrographs. The phase separated regions are analyzed by conducting the STEM-EDS mapping of the alloys. Bright-field (BF), high angle annular dark-field (HAADF) STEM images and the corresponding elemental mapping are compared. It has been observed that the nano-amorphous domains are uniformly distributed through out the sample. APT results give detailed information on the chemical composition and the spatial distribution of each element. The overall composition of the measured tip is found to be in good agreement with the nominal composition. The spatial atomic distribution analysis by APT revealed discontinuities for the main elements and the formation of clusters suggesting the occurrence of phase separation in these glasses.

Conclusions:

In summary, a new phase separated Zr-based MG has been successfully developed. The microstructure of phase separated nano-amorphous domains has been confirmed by sophisticated experimental characterization techniques including TEM and APT. The alloys form a two-glassy-phase structure. APT analysis revealed the formation of ~7 nm size clusters. The two-glassy-phase MG system free of toxic elements with high glass-forming ability may be used as a precursor for fabricating continuous nano-porous MGs and could be a promising candidate for implant applications.

TRIBLOCK POLY(2-OXAZOLINE)S WITH A FLUORINATED BLOCK AS A NEW PLATFORM FOR ADVANCED SELF-ASSEMBLY: CRYO-TEM STUDY

Sergey Filippov[1], Dr. Leonid Kaberov[2], Dr. Lubomir Kovacik[3], Prof. Richard Hoogenboom[4]
[1]DWI Institute of Interactive Materials, Aachen, Germany, [2]Friedrich Schiller University, Jena, Germany, [3]C-CINA, Biozentrum, University of Basel, Basel, Switzerland, [4]Ghent University, Ghent, Belgium

Poster Group 2

The synthesis of defined triphilic terpolymers with hydrophilic, lyophilic, and fluorophilic blocks is an important challenge as a basis for the development of multicompartment self-assembled structures with potential for, e.g., cascade catalysis and multidrug loading. A series of fluorinated 2-substituted-2-oxazoline copolymers with hydrophilic 2-methyl-2-oxazoline, hydrophobic 2-octyl-2-oxazoline, and fluorophilic blocks were synthesized in our group previously [1-5]. The presence of the blocks with the different nature in one copolymer structure facilitated self-assembly of the copolymers in water as observed by dynamic light scattering, and cryo-transmission electron microscopy. The nanoparticle morphology is strongly influenced by the order and length of each block and the nature of solvent, leading to nanoparticles with tuning structure as confirmed by Cryo-TEM. For the polymer that has no fluorinated tail formed primarily multi-layered vesicles (Figure 1A), which is in agreement with the DLS result. In contrast, the cryo-TEM analysis of the polymer solution with shortest fluorinated block showed a mixture of aggregating rod-like micelles and little-populated single-layered vesicles (Figure 1B). However, the extension of the fluoroalkyl chain length further decreased the relative content of the vesicles (Figure 1C). This trend is continued for copolymer with the longest fluorinated alkyl chain, which only showed isolated rod-like micelles with a small fraction of agglomerates composed of rod-like micelles, while vesicles were no longer observed (Figure 1D).
Figure 1. Cryo-TEM images of the investigated polymers. (A) The non-fluorinated diblock copolymer formed single- and multi-layered vesicles, together with short rod-like micelles. (B) The C8F17 and C) C10F21 copolymers formed single-layered vesicles and aggregates of rod-like micelles. (D) The C12F25 copolymer assembled into rod-like micelles only. Scale bars: 100 nm.
The reported poly(2-oxazoline) block copolymers with high fluorine content have high potential for future development of MRI contrast agents.

Poster Group 1

Neurological manifestations of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection represent a major issue in long coronavirus disease. How SARS-CoV-2 gains access to the brain and how infection leads to neurological symptoms are not clear because the principal means of viral entry by endocytosis, the angiotensin-converting enzyme 2 receptor, are barely detectable in the brain. Here, we investigated the neuroinvasive potential of SARS-CoV-2. By applying confocal microscopy and in cellulo correlative fluorescence and cryo–electron tomography, we reported that human neuronal cells, nonpermissive to infection through the endocytic pathway, can be infected when cocultured with permissive infected epithelial cells through tunneling nanotubes (TNTs). SARS-CoV-2 and multiple vesicular structures such as double-membrane vesicles, sites of viral replication, are observed inside TNTs between permissive and nonpermissive cells. Our data highlight a previously unknown mechanism of SARS-CoV-2 spreading, likely used as a route to invade nonpermissive cells and potentiate infection in permissive cells.

Interdiffusion-controlled phase formation at an interconnect interface during soldering

Sandra Gaertner[1], Dr. Harald Rösner[1], Apl. Prof Dr. Sergiy Divinskiy[1], Prof. Dr. Gerhard Wilde[1]
[1]Institute of Materials Physics, University Münster, Münster, Germany

Poster Group 2

Background incl. aims:
Soldering is a well-established method for creating permanent bonds between metal parts, often resulting in the formation of intermetallic compounds. For the purpose of soldering, various elements like Sn, Pb, Bi, Sb, Ag and Cu, or their alloys, are utilized in different compositions based on the respective field of application. The shift towards lead-free solder, driven by environmental regulations, has increased interest in Sn-based solder alloys. However, soldering interconnects involves complex processes related to material transport, phase stability, and phase transformation kinetics.
Methods:
In the present work, the interdiffusion and diffusion-controlled phase formation processes in a Sn-Sb solder alloy between a Ni-based layer with a minor Si amount and a Cu substrate were investigated using various electron microscopy techniques. Initial scanning electron microscopy analysis of cross-section samples provided an overview of the interface, including the Sn-Sb solder alloy. For detailed examination, focused ion beam techniques were employed to create electron-transparent samples for analysis using analytical transmission electron microscopy.
Results:
Examination of the untreated states of the Ni-based layer and the solder alloy allowed differentiation between the initial microstructure and changes post-soldering. The Ni-based layer exhibited a lamellar-type structure with a uniform elemental distribution perpendicular to the soldered interface, while the raw solder alloy consisted of a tetragonal β-Sn phase as a matrix and a trigonal SbSn phase. After the soldering procedure, CuSnNi and SnCu intermetallic compounds formed with various shapes, surrounded by the β-Sn matrix. The SbSn phase persisted as small inclusions. Additionally, the Ni-based layer initially shrank due to diffusive interactions with Cu and Sn, resulting in a thin film with increased Si content compared to the untreated layer, eventually leading to complete consumption of the Ni-based layer.
Conclusions:
This study highlights the intricate processes involved in Cu transport from the substrate through the solder material, emphasizing the significant role of Cu in forming intermetallic compounds. Together with Sn, Cu drives the transformation of the Ni-based layer towards complete consumption. In addition to elemental influences, microstructures play a crucial role in the Ni consumption process.

Machine Learning Algorithms for Tracking Analysis of Chloroplast Avoidance Movements

MSc Aleksander Luboński[1], Mr. Sławomir Samardakiewicz[1]
[1]Laboratory of Electron and Confocal Microscopy, Faculty of Biology, Adam Mickiewicz University, Poznań, Poland

Poster Group 1

Background incl. aims:
Plants use chloroplast movements to cope with environmental changes, particularly in response to high-intensity light stress. Chloroplasts relocate within cells, minimizing energy absorption and protecting the photosynthetic apparatus [1]. Monitoring chloroplast responses to light stress requires accurate measurement of their relocation dynamics. Computerized image analysis, combined with machine learning algorithms, has proven reliable and accurate in observing organelle movements [2,3]. Our study integrates traditional microscopic image analysis with machine learning approaches to track chloroplast trajectories during their response to strong blue light.
Methods:
The model plant Lemna trisulca L. [1] was used to analyze the chloroplast avoidance reaction. After a period of incubation in the dark, the plants were treated with strong blue light generated by a led illuminator (44µE m-2s-1 for 1 minute), followed by an analysis using an LSM510 confocal microscope with 633nm and 488nm laser light. Image series in the form of time-lapse photography were collected during periods of 15 minutes of observation. Once the images were obtained, the first step was to use the open-source software Fiji [2] (which is a new distribution of ImageJ), including the plugin to automate the process of tracking chloroplasts, TrackMate [3]. The software was used to improve image quality, detect objects and perform the tracking process. The resulting data from Fiji was used in a second analysis stage created in Python 3.10.9, using the Jupiter Notebook software. The aim of the second stage was to find patterns of chloroplast movement.
Result:
Using comprehensive trajectory analysis, the movement of chloroplasts during the avoidance movement in L. trisulca cells was shown to be curvilinear. Approaches using machine learning techniques including cluster analysis allowed the separation of two groups of chloroplasts. The features that distinguished these groups were the Confinement ratio and Mean straight-line speed (these are the parameters calculated within the TrackMate plugin). The first of the distinguished groups of chloroplasts was characterized by a high efficiency of movement from the starting point to the destination. This was due to the fact that, during the avoidance response, the chloroplasts moved along a roughly constant orientation, allowing them to move more efficiently away from the start point. These observations also had high values for the average velocity in linear movement. The second group obtained had a higher number of curve sections clustered near the starting point, which looked as if the chloroplasts were "circling" longer around the starting point of the movement. This translated into lower values for the Confinement ratio and Mean straight-line speed than in the observations of the first group. Irrespective of the two main patterns of chloroplast movement that were determined, chloroplast trajectories with transient features were also observed.
Conclusion:

The application of classical image analysis methods allowed information on the trajectories of chloroplast movements to be obtained. The collected data were used to perform a cluster analysis process which then allowed the determination of chloroplast movement patterns in the avoidance response. This example demonstrates that machine-learning algorithms in the analysis of chloroplast movement trajectories can significantly extend the capabilities of classical image analysis methods.

(In-situ) 3DED and other TEM Techniques Unravel (Ca,Sr)(Mn,Fe)O3-δ and LaxSr2-xMnO4-δ Structure-Property Relations in Redox Conditions

Daphne Vandemeulebroucke[1], Dr. Maria Batuk[1], Mr. Amirhossein Hajizadeh[1], Dr. Pascal Roussel[2], Dr. Myriam Wastiaux[2], Prof. Dr. Joke Hadermann[1]

PS-04 (2), Plenary, august 26, 2024, 14:00 - 16:00

Background
Many alternative energy applications involve inorganic crystalline solids exposed to redox conditions, e.g. solid oxide fuel cells (SOFCs) or chemical looping with oxygen uncoupling (CLOU). With the development of in-situ 3D electron diffraction (3DED) of solids at high-temperature in gas and vacuum conditions, great new potential is unlocked for unravelling structure transformations in such operational conditions, to understand the origins of e.g. high performance and degradation properties. Here, we investigated the influence of high-temperature reducing atmospheres on the structure of two such perovskite-based energy materials - CaMnO3-δ and LaxSr2-xMnO4-δ.

CaMnO3-δ is a perovskite with interesting properties as oxygen carrier in the CLOU process, i.e. a carbon capturing combustion technique that inherently separates expelled CO2 from air. The cycling stability and oxygen release temperature of this compound can be significantly improved by A or B site doping with e.g. Sr or Fe, but it has not yet been unravelled why. [1] [2]

Ruddlesden-Popper (RP) LaxSr2-xMnO4-δ are interesting electrode materials for symmetric solid oxide fuel cells (SOFCs) due to their electronic and chemical properties. Previously, they were reported from in-situ X-ray and neutron diffraction to remain stable upon heating to 700°C in H2 for $0 < x \leq 0.6$, although anomalously large atomic displacement parameters were found. Further, while all these structures had the same I4/mmm lattice, the x = 0.5 compound showed a higher conductivity in reducing environment (1.9 S cm −1), breaking the trend of the rest of the series (0.4, 0.5, and 0.8 S cm−1) which was not explained yet in literature. [3]

Methods
CaMnO3-δ, Ca0.75Sr0.25MnO3-δ, CaMn0.8Fe0.2O3-δ and LaxSr2-xMnO4-δ for x = 0, 0.25, 0.5, 0.75 and 1 were examined with in-situ and ex-situ 3DED, EDX, high-resolution HAADF-STEM and/or (mono STEM-) EELS. However, the investigation of oxides with in-situ TEM is not without obstacles. At temperatures above 700°C in reducing gas conditions, an extra silica layer is created in-situ around the studied oxide – as evidenced by EDX and EELS - due to a reaction coming from the Si3N4 of the heating chip. This shell can interfere with the reduction process, as shown from Mn valence determination by mono STEM-EELS. To overcome this problem, we performed a series of in-situ gas and vacuum experiments with LaxSr2-xMnO4-δ on graphene coated heating chips, in order to study the influence of various parameters and find the optimal conditions for in-situ TEM experiments on oxides in redox conditions, that can be directly linked to real-life energy applications.

Results
With in-situ 3DED in diluted H2 and in vacuum at 250°C-350°C, we captured the oxygen vacancy order in one of the intermediate oxygen deficient phases of CaMnO3-δ – i.e. CaMnO2.75 – and solved and refined its structure. We compared its structural transformations in H2 and vacuum high-

temperature conditions with those of the doped Ca0.75Sr0.25MnO3-δ and CaMn0.8Fe0.2O3-δ to explain the differences in performance on the level of the atomic lattice.

Also, 3D electron diffraction reveals the previously unreported structure transformations of La0.25Sr1.75MnO4-δ and La0.5Sr1.5MnO4-δ to an incommensurate 2D and 1D modulated structure respectively, but the amount of order in the crystals differs. Moreover, high-resolution HAADF-STEM shows a difference in defect structure: where the x = 0.5 compositions exhibits many higher order RP n = 2 layer defects, this is not the case for the x = 0.25 material. Those structural differences allow to explain the higher conductivity for La0.5Sr1.5MnO4-δ than for La0.25Sr1.75MnO4-δ . [4]

Further, in-situ high-resolution HAADF-STEM (in vacuum) and 3DED (in gas) at 700°C also detect the formation of a perovskite phase on the surface of both materials. From EDX, the layer is observed to be La rich, which leads to differences in thermodynamics between the surface and the bulk structure. [4]

Conclusions
Despite the additional challenges of in-situ TEM on oxides at very high temperatures in gas, the combination of in-situ and ex-situ 3DED, high-resolution HAADF-STEM, EDX and (mono STEM)-EELS offered a lot of new structural information on (Ca,Sr)(Mn,Fe)O3-δ and LaxSr2-xMnO4-δ in redox conditions. For these samples, their increased performance as CLOU oxygen carrier on doping, and differences in SFOC anode conductivity, were respectively linked to their differences in oxygen vacancy order and/or differences in defect structure. This illustrates the benefits of a combination of various in-situ and ex-situ TEM techniques to gain new insights in the structure-property relations of redox-based energy materials.

PS-01 (3), Lecture Theater 3, august 30, 2024, 14:00 - 16:00

Background incl. aims
Nanogranular gold films, when prepared by supersonic cluster beam deposition with a thickness just above the electrical percolation threshold, exhibit highly branched structure with a neuromorphic behavior reminiscent of biological neural networks, including resistive switching and adaptation. Such characteristics position these materials as viable substrates for neuromorphic computing. Despite their potential, the understanding of the underlying phenomena has been limited to electrical measurements and theoretical speculation. The objective of this study was to visually elucidate the morphological transformations that occur at the micro- and nanoscale within these films during electrical stimulation and to assess how these changes correlate with neuromorphic functionality.

Methods
Gold nanogranular films were deposited at approximately 17 nm thickness to balance electrical conductivity with TEM imaging suitability. These films were then subjected to in situ biasing within a two-electrode configuration. High temporal resolution imaging was conducted using a CMOS direct detection camera, operating at a controlled low electron dose. The morphology of the entire area between electrodes was observed during sequential electrical stimulations—first across a voltage ramp and then at a constant voltage. Additionally, in situ heating TEM imaging was applied, observing the films under thermal stress at both high resolution and low magnification.

Results
Initial in situ biasing caused the localized de-percolation effect shown in figure [1], and characterized by the retraction of gold branches without mass loss, leading to the formation of isolated gold islands. This morphological adaptation was highly localized and accompanied by the development of small, dense gold structures. Upon global thermal stimulation, the films underwent a more extensive de-percolation, resulting in the creation of distinct, polycrystalline gold islands across the whole heating substrate. This behavior is akin to that observed in atom-assembled gold films. The in situ TEM imaging revealed the likely occurrence of extremely intense and localized hot spots, whose temperature and extent appear to grow with increased voltage and may induce localized melting, even possibly capable of disrupting the amorphous silicon nitride substrate when the highest voltage and temperature are reached [1].

Conclusions
The study presents a novel visual insight into the morphological dynamics of nanogranular gold films under electrical and thermal stimuli, suggesting that intense, localized hot spots may play a critical role in neuromorphic behavior. The findings highlight the need for further exploration of the local

temperature within these hot spots, the role of electromigration and Joule heating, and the impact of the substrate on the film's behavior. In situ TEM imaging has proven invaluable in expanding our understanding of the physical phenomena driving the unique electrical characteristics of metal nanogranular films, offering implications for the advancement of materials with neuromorphic properties.

Poster Group 2

Background
Transmission electron microscopy (TEM), especially at cryogenic temperature, is largely used for studying biological macromolecules at high resolution and for 3D reconstruction. The main difficulty of TEM imaging of biological samples is the weak amplitude contrasts due to electron diffusion on light elements. Achieving 3D high-resolution reconstructions implies the acquisition of a huge number of TEM micrographs followed by a time-consuming image analysis. This TEM constraint could be overcome by imaging the phase shift of the electron beam resulting from its interaction with the sample.
Methods
In our work, we developed two TEM techniques, off-axis electron holography and in-line electron holography, for phase image extraction of biological samples. We mainly used unstained T4 and T5 bacteriophages as model samples which were deposited on graphene grids provided by Sara Bals's team (Antwerp University, Belgium) for room temperature experiments, while we used lacey grids for cryogenic temperature experiments.
Results and Conclusions
Thanks both to recent developments carried out at CEMES on off-axis holography [1,2] and to the direct electron detectors performances, we show on one hand that off-axis holography enables us to retrieve the phase shift information that the electron undergoes when interacting with the low-Z biological samples (figure 1 a-d). On the other hand, thanks to the in-line holography capability to be performed on any microscope, as well as the automation of a cryogenic electron microscope equipped with a direct electron detector, we show the ability of this technique to resolve high-resolution structural details (figure 1 e-f) with very low noise levels at low electron dose. We thus demonstrate the possibility of both techniques to obtain highly contrasted phase images of unstained samples both at room and cryogenic temperatures, in addition to an improved signal-to-noise ratio. Furthermore, since a change in electric charges affects the phase shift and can be detected by electron holography, we show a novel potential application using both off-axis and in-line electron holography methods, to measure electrostatic variations on biological specimens. This was evidenced in off-axis holography by measuring the phase shift changes at the capsid between phages treated with spermine, a multivalent cation that diffuses inside the capsid and neutralizes the DNA, and a non-treated T5 phages (Figure 1d). This electrostatic change was also observed locally by in-line holography by studying at high resolution the phase shift pattern of the tail, and globally by studying the phase shift signal around a full capsid and comparing it to the one around an empty one (figure 1f). More work is needed to fully take advantage of these microscopy phase imaging techniques

Poster Group 2

Off-axis electron holography is a well-established method for the investigation of projected potential distributions down to atomic spatial resolution. However, in the case of in-operando (electrical biasing) investigations of externally controlled semiconductor nanostructures, parasitic modulations of the electron wave occur due to long-range electrostatic stray fields [1]. In addition, a well-known problem is the alteration of the sample during preparation using a focused ion beam (e.g. ion implantation, surface amorphization or generation of conducting surfaces), which also severely influences the potential distribution within the sample [2]. Both effects have a particular impact in the direction of the electron beam as well, which makes a quantitative analysis particularly difficult. Standard approaches to resolve the entire potential distribution involve projective tilt series and their tomographic reconstruction [3], which entail a significant measurement effort (e.g. sample tracking or long-time stability) and instrumentational limitations (e.g. limited tilt angle (i.e. missing wedge), interior Radon transform or parallax displacement), in addition to extensive simulations (e.g. FEM or DEM), which are highly computationally intensive and require rarely given knowledge of the microscopic charge carrier distribution.
Here, a simple and intuitive model (SIMP) for the approximation of such potential distributions inside and outside nanostructured FIB-prepared samples of a p-n junction, requiring a limited set of parameters, is presented. The model uses only independent convolutions of an initial potential distribution (e.g. analytic textbook models) with a Gaussian kernel (see attached figure), allowing the reconstruction of the entire potential distribution from only one measured projection (electron hologram). In addition, various contacted semiconductor nanostructure samples (TEM-lamellae) are produced in a systematic approach using FIB under varying preparation parameters (i.e. currents and acceleration voltages of the ions) to evaluate the proposed model.
In comparison with FEM-simulations, representing an established simulation method, it can be shown that the self-developed model is able to accurately approximate the 3D electrostatic potential distribution of various contacted TEM-samples, whereby the computational complexity can be significantly reduced with respect to FEM-simulations (i.e. ~1000x faster with ~1/1000th of the memory usage at ~5000x more nodes). An excellent agreement can likewise be observed in comparison with electron holographic and tomographic investigations considering experimental restrictions, revealing the real potential distribution in propagation direction of the electron beam. By this, a significant reduction of the required computational power as well as a drastically simplified measurement process is achieved, paving the way towards quantitative electron holographic investigation of electrically biased semiconductor nanostructures. In particular, the latter can in turn also be used to understand the exact effects of the FIB-preparation (e.g. implantation concentration or implantation depth) on the sample, thus leading to improved preparation strategies.

Differential Phase Contrast Microscopy and Atom Probe Tomography of Ferromagnetism in High-Entropy Alloys

Ms. Shabnam Taheriniya[1], Dr Harald Rösner[1], Mr. Gerhard Wilde[1]
[1]Institute of Materials Physics, University of Münster, 48149 Münster, Germany

PS-02 (1), Lecture Theater 5, august 28, 2024, 10:30 - 12:30

Background incl. aims
High-entropy alloys (HEAs) are emerging as promising materials for future applications due to their high configurational entropy and diverse local atomic environments. Among the four core effects in HEAs, the concept of the 'cocktail effect', resulting from multi-principal alloy design, is particularly intriguing as it can lead to the emergence of new properties. When elements with different structural, kinetic, and ferromagnetic properties are combined in single-phase or nanocomposite HEAs, unexpected interactions and the emergence of new properties or phases can occur, surpassing predictions based on simple mixtures. Certain equiatomic alloys, initially paramagnetic, have been found to exhibit ferromagnetic properties after undergoing deformation processes like rolling or cold-working. This unexpected behavior has been attributed to changes in the local atomic environment and the creation of defects during deformation, resulting in the formation of ferromagnetic clusters. Understanding the mechanisms behind deformation-induced ferromagnetism in these alloys is the aim of this contribution.
Methods
In this study, single phase (CoCrFeMnNi) and nanocomposite HEAs (CoCrFeMnNi and HfNbTaTiZr) were processed using high-pressure torsion (HPT), subjecting the samples to a constant pressure of 9 GPa either as a single disk or stacked disks, with the top anvil rotating at 1 rpm at ambient temperature for up to 15 revolutions. Vibrating sample magnetometry (VSM) confirmed that HPT processing induces the development of ferromagnetic properties. The distribution and orientation of magnetic domains post-deformation were examined in detail using differential phase contrast scanning transmission electron microscopy (DPC STEM), analytical TEM and atom probe tomography (APT) analysis.
Results
Analytical TEM indicates that while the nanocomposite HEA shows significant phase sep-aration due to co-deformation, its saturation magnetization measured by VSM is lower than that of the HPT-processed Cantor alloy. The pronounced phase separation in the nanocomposite HEA leads to lamellar-like alignments of NiCo-rich ferromagnetic and Cr-rich anti-ferromagnetic domains observed by DPC, reducing the overall magnetic moment. Conversely, the absence of such phase separation in the HPT-processed Cantor alloy results in comparable coercivity. APT analyses reveal that this difference arises from the deformation-induced local enrichment of ferromagnetic elements, particularly Ni, showcasing the 'cocktail effect' in HEAs where inter-element interactions lead to unique magnetic behavior.
Conclusions
Our study demonstrates that HPT processing of HEAs induces a transition from paramagnetic to ferromagnetic states at ambient conditions. Deformation-induced ferromag-netism can be explained by the 'cocktail effect' in HEAs, where the formation of ferromagnetic particles is linked to deformation-induced element-selective atomic migration and local enrichment of ferromagnetic elements.

Optimizing micrograph contrast in multicomponent systems at low-voltage scanning electron microscopy

Asia Matatyaho Ya'akobi[1], Irina Davidovich[1], Yeshayahu Talmon[1]
[1]The Department of Chemical Engineering and The Russell Berrie Nanotechnology Institute (RBNI), Haifa , Israel

Poster Group 2

Background incl. aims:
Scanning electron microscopy (SEM) is one of the most widely used electron microscopy techniques in science and engineering. Although the SEM was originally intended for operation at low beam acceleration voltages (BAV), it was only possible to operate at low beam energies decades after the first commercial SEM was available. Hence, most of the pioneering studies of electron-specimen interaction physics have been conducted at BAVs above 5 kV. In recent years, the reliable and easy-to-operate field emission guns (FEGs), and the improved optics, vacuum, and detectors in modern SEMs, have led to the widespread use of low-voltage SEM. However, studies in the low BAV range remain limited, and there is a lack of awareness of their importance. The purpose of this study is to investigate the effects of SEM operational parameters and specimen properties on micrograph contrast at BAVs below 2 kV.
Methods:
The modern SEMs, equipped with the in-the-column ("InLens" in the Zeiss lingo) secondary electron detector for high-resolution imaging, are flexible instruments allowing operation over a wide range of parameters. Two of the fundamental SEM operational parameters are the BAV and the working distance (WD). Here, we investigate systematically the effect of the BAV and the WD on the InLens micrograph contrast. We image a variety of specimens, consisting of conductive (carbon nanotubes) or insulating (boron nitride nanotubes) materials, or their combination, on conductive (silicon wafer) and insulating (glass slide) substrates. To include all combinations, we imaged 6 specimen types, each specimen was imaged at 3 different BAVs, where at each BAV the micrograph was acquired at 3 different WDs.
Results:
Our results show that the InLens micrograph contrast is directly affected by the BAV and the WD, and by the specimen electrical conductivity properties. We analyze the contrast changes and explain them through the changes in the secondary electron signal at different conditions. We demonstrate that choosing adequate SEM operational parameters is essential for obtaining an optimal micrograph contrast, and thus for obtaining complete information of the specimen. Moreover, in the case of insulating specimens, we demonstrate the possibility of avoiding specimen charging without using conductive coating.
Conclusions:
For proper selection of the SEM operational parameters, one should understand how micrograph contrast changes with BAV and WD, and be able to adjust them according to specimen properties. This way, an optimal micrograph with sufficient contrast but without charging artifacts can be obtained. As our study includes a variety of systems combining conductive and insulating components, its conclusions can be easily adopted for a wide range of systems and studies.

Vibration-Corrected Electron Ptychography

Anton Gladyshev[1,2], Mr. Johannes Müller[1,2], Dr. Benedikt Haas[1,2], Prof. PhD Christoph Koch1[1,2]
[1]Humboldt-Universität zu Berlin, Berlin, Germany, [2]Center for the Science of Materials Berlin, Berlin, Germany

IM-03 (3), Plenary, august 29, 2024, 10:30 - 12:30

Background incl. aims

Far-field electron ptychography is considered to be one of the most powerful phase retrieval techniques currently available for electron microscopists. Recently it was shown that ptychography is capable to surpass the Abbe resolution limit [1] and resolve specimens features as fine as the blurring due to the vibrations of the atoms [1]. A rather simple mathematical model of coherent diffraction pattern formation standing behind conventional algorithms [2,3] does not account for any motion or superposed states [1,2,3]. In order to overcome the resolution limit caused by the lattice vibrations we utilize the mixed-object formalism initially proposed in 2013 for X-rays [3], but never applied to electron microscopy data without assuming explicit atom positions [4]. In contrast to conventional ptychography [1,2,3] that treats a single transmission function of a specimen, mixed-object ptychographic reconstruction considers a sequence of superposed transmission function states, each producing a coherent diffraction pattern via a multislice simulation [1,2]. The total diffraction pattern corresponding to the entangled system is formed as an incoherent sum over the states [2,3,4].

Methods

For the tests of mixed-object ptychography we used a 4D-STEM dataset [1,2] of a monolayer MoS2 acquired in the Nion Hermes microscope at an accelerating voltage, convergence semi-angle, scan step and electron dose of 60 kV, 33 mrad, 0.2 Å and 5.3*10^6 e-/Å^2, respectively. To evaluate the resolution of the ptychographic reconstructions we propose a novel approach, akin to the Young fringe resolution test widely applied in TEM imaging [5]. We perform two ptychographic reconstructions with random initial guess for the object, e.g. uniform prior. Then the two independent results are shifted with respect to each other and the Fourier intensity of the difference is computed. The arising interference fringes indicate the range of spatial frequencies identical in the two results, allowing to conclude how deterministic a particular reconstruction is. Further, in contrast to conventional resolution tests, e.g. visibility of the Fourier peaks [1], the proposed approach allows to include aperiodic features that are crucial for a moving specimen.

Results

Assuming a single illumination mode [1,2,3] we conducted pairs of ptychographic reconstructions in two scenarios: one involving a single-state and the other involving 10 states of the transmission function. After 500 iterations of the gradient-descent [2] the achieved resolution was estimated. As a result, two independent pure-state reconstructions appear to produce identical information up to 1.9 Å^-1, while the mixed-object reconstructions contain deterministic information up to 2.3 Å-1. Figure 1 shows a comparison between pure- and mixed-state psychographic reconstructions.

Figure 1. Comparison of pure-state (upper row) and mixed-state (lower row) ptychographic reconstructions. Panels an and d show phases of a single-state reconstruction and an average over 10 states, panels b) and e) show the Fourier intensities (averaged over the states). The panels c and f show the results of Young fringe resolution test. The information limit of 2.3 Å^-1 denoted by the

white circle was surpassed only by the mixed-state ptychographic reconstruction. The colorbar on the left side of the figure refers to the values of the phase in a) and d), the colorbar on the right refers to the Fourier intensities in b), c), e) and f).

Conclusions

Even with a monolayer specimen that is not supposed to produce a noticeable amount of incoherent scattering, we show that considering multiple entangled states of the transmission function makes the underlying model more realistic and improves the quality of the ptychographic fit. Thus, we liberate model-free ptychography from atomic vibrations, its last known resolution limit [1,2].

Background incl. aims

Far-field iterative electron ptychography [1,2,3] is a phase retrieval technique offering atomic scale imaging in scanning transmission electron microscopy (STEM) [4,5]. It fits an electrostatic potential of a specimen to a set of diffraction patterns collected while illuminating overlapping areas of its surface with a convergent beam [1,2,3,5]. Despite its rapid development, ptychography suffers from several practical challenges, particularly from the massive amount of data that is required to achieve a high degree of redundancy to solve the phase problem [2]. Our study addresses this limitation by proposing a lossy compression method for diffraction patterns [2] utilising virtual STEM detectors [2,4].

Methods

A 92 Å thick atomistic model of a silicon crystal containing a 60° edge dislocation dissociated into a stacking fault bounded by a 30° and 90° partial dislocation [5] was used to simulate a 4D-STEM [1] dataset with qstem [5], at an accelerating voltage of 60 kV, convergence semi-angle of 30 mrad and a scan step of 1 Å, including thermal diffuse scattering, an effective source of size 0.5 Å and a finite electron dose of 104 e-/Å^2. To perform electron ptychography we utilize an in-house written gradient-based optimization code [3] and use 4 slices of the transmission function in order to account for multiple scattering [1,2,5].

Our compression approach relies on virtual detectors [2,4]. With a single 4D-STEM detector they allow for a simultaneous recording of multiple signals, such as virtual annular dark- and bright-field (vADF and vABF), or centre of mass (COM) signals. In contrast to physical detectors, the virtual ones offer a flexibility to adjust their shapes to closely mimic actual diffraction patterns, facilitating a more efficient compression [2]. In an uncompressed scenario [1,2,3] the goal of an iterative ptychographic algorithm is to minimize the summed squared error (SSE) between the 4D-STEM dataset and the diffraction patterns generated by algorithm [1,2,3]. With a compressed data we modify the algorithm to predict the signals instead of the diffraction patterns via an additional known convolution layer [2] and aim to minimize the SSE between them and the measured signals of virtual detectors.

Results

In Figure 1 we compare three sets of virtual detectors for the bright field of the diffraction patterns: first 36 Zernike polynomials, 45 binning squares each 7x7 px wide and 15 virtual detectors generated via the Gram-Schmidt algorithm [2] from the diffraction patterns acquired at the positions indicated by the x-markers in the panel c). The dark field of the diffraction patterns was described via a single vADF detector in all three cases. For each compression option we show 6 bright field virtual detectors in panels e)-v) and compute the Fourier ring correlation with the projected potential used for the simulation of the dataset.

Figure 1 Comparison of ptychographically reconstructed projected phases of a silicon crystal from compressed 4D-STEM data. a), b) and c) show the results for first 36 Zernike polynomials, 45 binning detectors and 15 data-dependent virtual detectors, respectively. For each of three options we show 6 virtual detectors in e)-v). For data-dependent detectors we denote the scan positions used to generate them via lime-colored x-markers in c). The projected electrostatic potential used for a simulation of the dataset is presented in d). Further we compare the Fourier ring correlations between the reference potential and three reconstructions in w).

Conclusions

The diffraction patterns in the initial dataset were 500x500 px wide. Our findings reveal that through the application of virtual detectors, including Zernike polynomials, binning squares, and detectors generated via the Gram-Schmidt algorithm, we can achieve a data compression ratio [2] of 5,000 to 15,000. Most importantly, our results demonstrate that atomic resolution in ptychographic reconstructions can be maintained even under conditions of partial spatial coherence and limited electron dose. The proposed compression approach takes the specific geometry of diffraction patterns into account and retains a sufficient amount of the "intact" information [2]. No specific constraints, e.g. a regularization, were used, but as previously shown [1], this could improve the quality of the reconstructions.

Advanced Brillouin fibre probes for in situ Brillouin imaging

Irina Kabakova[1]
[1]School of Mathematical and Physical Sciences, University of Technology Sydney , Sydney , Australia

Poster Group 1

Background
Brillouin imaging (BI) has become a valuable tool for micromechanical material characterisation, thanks to extensive progress in instrumentation in the last few decades. This powerful technique is contactless and label-free, thus making it especially suitable for biomedical applications. Nonetheless, to fully harness the non-contact and non-destructive nature of BI, transformational changes in instrumentation are still needed to extend the technology's utility into the domain of in vivo and in situ operation, which we foresee to be particularly crucial for widespread usage of BI, e.g. in medical diagnostics and pathology screening. This talk reports on the progress in fibre-optic Brillouin probe design and fabrication, as well as provides outlook for fibre-based Brillouin imaging.

Methods
Two approaches in constructing Brillouin fibre probes are tested: 1) using a hollow core fibre (figures A and B) and 2) dual fibre probe with a 3D printed micro-lens system (figure C). The spectroscopic detection is done using a 6-pass scanning Fabry-Perot interferometer (TFP1, Table Stable). The results are analysed using home-build software in Matlab.

Results
The main challenge in constructing a fibre probe for Brillouin imaging is the strong back-scattered light generated in the fibre itself. Although this fibre signal appears in the frequency band that is far from the frequency region of interest (associated with biologically relevant signals), the strength of the fibre back-scattering is many orders of magnitude higher than that coming from the biological sample, thus making the detection non-trivial. Several approaches to fibre-integrated Brillouin imaging will be discussed, including: (1) single hollow-core fibre (figures A-B) and (2) two-fibre probe with a micro-lens system design (figure C). In the single fibre approach, the fibre is chosen to have a hollow core that in theory prevents background scattering. The performance of the hollow-core fibre Brillouin imaging system is evaluated by mapping a biological phantom consisting of a hydrogel spheroid and media. The scattering efficiency in this demonstration is found to be comparable with the bulk-optical Brillouin microscopy systems.
Two-fibre Brillouin probe approach can solve the challenge of the spurious scattering background due to separation of the illumination and detection paths. It, however, requires specialised solutions for light focusing that preserve both tight focusing into the sample and high collection efficiency for the scattered light. Such a solution based on a 3D printed micro-lens, specifically engineered for Brillouin imaging application, will be discussed and the scanning results using the dual-fibre probe will be demonstrated.

Conclusion
In conclusion, different strategies for achieving fibre-integrated Brillouin imaging are tested and compared. Each strategy exhibits advantages and limitations and the choice will depend on the endoscopic application in mind.

DQE measurement for TEM detectors: from the key parameter to an ambiguous estimate

Olivier Marcelot[1], Mme Cecile Marcelot[2]
[1]ISAE-SUPAERO, Toulouse, France, [2]CEMES-CNRS, Toulouse, France

Poster Group 1

Background incl. aims
Nowadays, the performance of CMOS electron detectors for transmission electron microscopes (TEM) are mainly compared by means of a unique parameter, the detective quantum efficiency (DQE). This parameter is largely promoted by camera providers, and is given as a unique number while it is known to strongly depend on the electron dose. In addition, the DQE calculation method may influence the result, as it will be presented in this study. Consequently, several DQE values can be found for one detector, and one should wonder if a unique DQE is the correct figure of merit for electron detectors.
One aim of this work is to demonstrate that the most commonly used method to calculate the DQE leads to strong uncertainties. To achieve this goal, measurements are conducted on an electron detector and a model is developed. Then, the second aim is to provide recommendations and trustable alternatives for detector comparisons.

Methods
The DQE depends on the spatial frequency w and is generally expressed as a component DQE(0) at the spatial frequency (0) times components depending on the spatial frequency, as in the following:
$DQE(w)=DQE(0)xMTF(w)^2/NTF(w)^2$
where MTF is the modulation transfer function and NTF the noise transfer function. MTF and NTF are well established so this work focuses on the DQE(0) calculation.
DQE(0) can be estimated by means of the full calculation of the various noise sources, including the shot noise, the gain variance "σg", the Fano noise "F", the dark current "DC" and the readout noise "NRO":
$DQE(0)=g^2/(g^2\ (1+F)+\sigma g^2+(t\cdot DC+NRO^2)/n\_i\ )$
where "n_i" is the number of incident electrons, "g" is the detector gain, "t" the integration time
The gain is extracted thanks to a comparison between the integrated electrons and the beam current measured with a Faraday cap, and the gain variation is estimated from the spatial variance of a flat field picture. While these measurements are not too complex, it is much more difficult to measure the Fano noise. It can be estimated with the standard deviation of simulated deposited energy distributions. Then, the readout noise and the dark current are measured from several acquisitions performed in dark condition.
Since several years, a simplified method has been preferred for the DQE(0) estimation, and relies on the direct measurement of the detector output noise by means of the spatial variance of a flat field image. However, in this case, the large electron hole distribution generated by the beam is spread between pixels and the spatial variance is underestimated. To solve this issue, McMullan proposed in 2009 to extract the spatial variance on binned pixels, for which a saturation is achieved if the binning number is large enough. This method is referred as the McMullan method subsequently.

Results

A Gatan-Rio-16 camera mounted on a JEOL-2100 FEG microscope is used for this study. This detector being an indirect one, the Fano noise is due to the scintillator and is estimated at 0,25. The electron dose is chosen in order to achieve the half full well capacity of the detector. For n_i=107, DQE(0)_FullCalculation=0.79 and DQE(0)_McMullan=0.62.
These two results are quite different and it is supposed that the McMullan method over-estimates the output noise and therefore gives a lower DQE(0).
With the intention to demonstrate it, a simple model is built, based on the generation of a shot noise and a gain variation leading to a similar noise distribution acquired with the Gatan-Rio-16 camera. For this purpose, the standard deviation of the noise is adapted is order to get an extracted variance identical to the measured one. In addition, a Gaussian blur is added with the intention to simulate the electron spread over the pixels and is parametrized in a way to get the same saturation of the variance according the binning number. The resulting noise distribution does not match the measured one which is much more extended and show pixels with much higher noises.
Actually, the McMullan method requires to subtract two flat field pictures in order to remove dead and saturated pixels, and the fixed pattern noise which avoid a correct variance saturation. However, it is necessary to consider other defective pixels, such as the hot pixels with a higher gain. These defective pixels are not removed by the subtraction of two flat field images and may distort the variance extraction. To demonstrate it, the previous model is modified and one population of hot pixels is introduced. The hot pixels ratio and gain are adjusted in order to obtain a noise distribution similar to the one measured with the Gatan-Rio-16. A hot pixel density of 6×10^(-4) with a high gain of 30 lead to a noise distribution comparable with the experiment, and the spatial variance extracted with hot pixels is 50% higher compared to the one extracted without hot pixels (see the figure 1).
Therefore, it is demonstrated that the commonly used McMullan method leads to an underestimation of the DQE(0) because of hot pixels. Other limitations are found and discussed, based on the fact that the noise is distributed on a statistical population of hot pixel which may give different results at every DQE measurement.
Consequently, the DQE(0) should not be used as a unique number for the detector comparison because it depends on the electron dose, on the experimental condition and on the used method. In order to fairly compare detectors, it is therefore recommended to use other parameters clearly defined and measurable: the gain for an information on the sensibility, the MTF for the spatial resolution and the dark current for the radiation hardness.

Conclusion
The DQE(0) is measured on a commercial camera with two methods and it comes that the McMullan method, largely preferred by the camera providers, leads to large uncertainties. By means of a model, it is demonstrated that detector hot pixels induce an over-estimation of the output noise leading to the DQE under-estimation with the McMullan method.
The DQE suffering from large uncertainties it is recommend to use the gain, the MTF and the dark current for fair comparisons between detectors.

Fractal: An open-source framework for reproducible bioimage analysis at scale using OME-Zarrs

Dr. Joel Lüthi[1]
[1]BioVisionCenter, University of Zurich, Zurich, Switzerland

Poster Group 2

Background incl. aims
Analyzing large amounts of microscopy images in a FAIR manner is an ongoing challenge, turbocharged by the large diversity of image file formats and processing approaches. Recent community work on an OME next-generation file format [1] offers the chance to create more shareable bioimage analysis workflows. Building up on this and to address issues related to the scalability & accessibility of bioimage analysis pipelines, the BioVisionCenter, a newly-created structure of the University of Zurich & the Friedrich Miescher Institute for Biomedical Research, is developing Fractal [2], an open-source framework for processing images in the OME-Zarr format.

Methods
The Fractal framework consists of a server backend & web-frontend that handle modular image processing tasks. It facilitates the design and execution of reproducible workflows to convert images into OME-Zarrs and apply advanced processing operations to them at scale, without the need for advanced expertise in programming or large image file handling.

Results
Fractal allows users to orchestrate the analysis of terabytes of high content microscopy images on high performance clusters. It comes with pre-built tasks to perform instance segmentation with state-of-the-art machine learning tools, to apply registration, and to extract high-dimensional measurements from multiplexed, 3D image data. We are providing a web front-end to facilitate user interactions with Fractal and streamline the submission of image analysis jobs to a slurm cluster. Finally, by relying on OME-Zarr-compatible viewers like napari [3], MoBIE [4] and ViZarr [5], Fractal enables researchers to interactively visualize terabytes of image data stored on their institution's remote server, as well as the results of their image processing workflows.

Conclusions
We present the open-source framework Fractal for FAIR image analysis at scale in the OME-Zarr format.

Poster Group 1

Whole organ 3D light sheet fluorescence microscopy (LSFM) is gaining popularity in preclinical pharmacological research to map the expression of new drug targets, characterize compound biodistribution, visualize drug induced changes in neuronal activation and to demonstrate the efficacy of pharmaceuticals to alter pathological changes in animal models of human diseases. Its broad applicability arises from the capability of imaging structures ranging from a few micrometres to centimetres, possibility of visualizing multiple fluorophores simultaneously and detecting subtle differences in their intensities. As such, LSFM bridges the gap between traditional in vivo imaging modalities and high-resolution histology and confocal microscopy of fixed tissue samples. Still, sample preparation for LSFM depends heavily on the tissue type and the desired imaging endpoints. Testing multiple parameters is often time-consuming as the protocols can take months to complete. Here we demonstrate a stepwise decision matrix to select suitable sample preparation steps for all rodent organs to characterize both compound distribution, mRNA and protein localization. We demonstrate pretreatment steps most suitable to visualize compound biodistribution, show the improved protocol to achieve uniform antibody staining in rat samples and present the workflow for 3D LSFM of hearts and other peripheral organs. Finally, we successfully expand the proposed decision matrix to include minipigs brains, a large gyrencephalic brain.

Unlocking Macroscale Solutions with Nanoscale Information: Towards Next-generation Optoelectronics

Prof Elke Debroye[1], Mr. Handong Jin[1], Mr. Amitrajit Mukherjee[1], Mr. Sudipta Seth[1], Mr. Johan Hofkens[1]
[1]KU Leuven, Department of Chemistry, Leuven, Belgium

Poster Group 2

Background incl. aims
Metal halide perovskites are a class of semiconductors that have garnered a tremendous amount of attention for application in optoelectronic devices. These low-cost materials exhibit outstanding properties, such as efficient light absorption, tunable emission, and good charge carrier transport. As an example, perovskites have accomplished a rapid rise in solar power conversion efficiency to over 25% in less than a decade, outperforming the conventional silicon solar cells. However, the fundamental understanding of their intrinsic properties and of the impact of defects on their photophysical performance and stability is lagging behind. We aim to exploit this nanoscale information to further improve the materials' applicability.
Methods and Results
Different synthesis strategies are applied to obtain perovskite nanocrystals with slight varieties in composition and structure. In this talk, I will focus on how we apply a set of advanced spectroscopic and correlated microscopic tools to detail the dynamics of the photogenerated charges and defects that govern the optoelectronic performance. Moreover, the stability of the corresponding materials will be discussed, and a novel approach to monitor device stability will be presented.
Conclusion
It will become clear that it is important to rationally micro-engineer the perovskites' chemistry, structure, and carrier dynamics toward an improved material platform for next-generation optoelectronics.

Comprehensive 3D Characterization Workflow for Solid Oxide Cells

Dr Bartlomiej Winiarski[1], Patrick Barthelemy[2], Chengge Jiao[3], Dirk Laeveren[3], Dalton Cox[4], SA Barnett[4]
[1]Thermo Fisher Scientific, Brno, Czech Republic, [2]Thermo Fisher Scientific, Waltham, USA, [3]Thermo Fisher Scientific, Eindhoven, The Netherlands, [4]Northwestern University, Evanston, USA

Poster Group 2

Background

Performance and durability of solid oxide cell (SOC) electrodes depend heavily on their porous microstructure properties and evolution over time. Ga+ FIB-SEM tomography has been pivotal for reconstructing SOC microscopic structures with nanometric precision [1], albeit limited to small volumes. With the emergence of Plasma FIB-SEM (PFIB-SEM), offering access to significantly larger material volumes [2], SOC microstructure investigation has taken a leap forward.
The porous nature of SOC microstructures poses challenges during both data collection and processing, resulting in artifacts like FIB curtaining and back-pore issues. Though techniques such as pressure-filling pores with resin [3] and rocking polish [2] mitigate these, electron charging effects persist. Deep Learning (DL) methods have shown promise in addressing back-pore issues [4], but challenges remain in electron charging compensation.
Post-segmentation, serial-sectioned SEM images undergo further processing to create 3D digital representations. This involves numerical simulations incorporating morphological parameters like tortuosity and constrictivity, crucial for understanding transport properties. Various software packages aid in this 3D characterization process [5].
This contribution presents a complete workflow for SOC microstructure characterization, from 3D reconstruction to comprehensive quantification. Using a Plasma FIB-SEM platform and automated serial sectioning software, a large 3D volume of SOC electrode is obtained, enabling detailed analysis. Advanced SEM imaging techniques coupled with DL-based segmentation streamline data processing, significantly reducing workflow time.

Methods

To demonstrate the workflow (Figure 1), we characterize a fresh solid oxide fuel cell (NYDC-55-3-0). Using the Plasma FIB-SEM platform and automated serial sectioning software (Auto Slice and View 5 - ASV5), we collect a large 3D volume (180 × 150 × 30 µm³) with a voxel size of 32 × 32 × 50 nm³. The Xe+ plasma beam current of 60 nA @ 30keV serial sections the specimens with a ±3° beam rocking motion and a 25 nm cut advancement. After each odd PFIB cut, SEM images are simultaneously acquired perpendicular to the cut face using a through-lens detector (TLD) for secondary electrons (SE) and a retractable concentric backscattered electron detector (CBS) for backscattered electron images. We utilize an SEM current of 200pA @ 2keV high tension and a 5 µs pixel dwell time to exploit the charge contrast phenomenon captured by the TLD-SE detector, enabling the separation of percolated and non-percolated Ni. The backscattered electron images from the CBS detector highlight voids and YSZ grains. The activated ASV5 auto functions for SEM, including source tilt, lens alignments, stigmatisms, focus, and image matching for drift correction, ensure consistent imaging conditions throughout the ASV run. By employing auto image matching for drift correction and SEM imaging at the normal angle to the cut face, we maintain volume-lossless conditions in the 3D image stack before data post-processing.

Results
We developed automated Avizo recipes to streamline data processing, analysis, and enable consistent and reliable data quantification and 3D visualization. The image stack doublets are subjected to denoising and segmentation into Ni, YSZ, and Voids using DL models [6], which also distinguish between percolated and non-percolated phases. The recipes calculate various spatial parameters (Figure 2) such as tortuosity [7], TPBs (total length, length/volume), phase volume fractions, percentage of non-percolating for each phase, and surface area/volume for Void|YSZ, Void|Ni, and YSZ|Ni. Notably, recent advancements in SEM image post-processing and denoising using DL algorithms in Avizo software have reduced SEM imaging time by 50%, resulting in a 25-30% reduction in the total acquisition time for the entire dataset.

Conclusion
This study shows comprehensive workflow that harnesses deep-learning predictions, encompassing the entire process from PFIB-SEM-based 3D microstructure analysis to meticulous quantification, illustrated through the examination of a freshly prepared solid oxide fuel cell. Our innovations have led to a thousandfold increase in image data acquisition volume compared to previous studies, all while maintaining a consistent voxel size. To ensure robust identification of material constituents, we simultaneously acquired CBS BSE and TLD SE images, ensuring 99.99% confidence. Key focuses include precise specimen preparation, optimizing PFIB-SEM setup for serial-sectioning, SEM image acquisition, DL-based post-processing and segmentation, recipe-oriented 3D quantification of morphological parameters, and report generation. Advanced SEM imaging techniques, coupled with automation and recent advancements in SEM image post-processing and segmentation using ML algorithms, streamline the characterization process, significantly reducing workflow execution time.

Optimized Bright Field STEM Imaging for Detecting Molecules absorbed within Zeolite Pores

Yu Xia[1], Mr. Tom WIllhammar[1]
[1]Department of Materials and Environmental Chemistry, Stockholm University, Stockholm, Sweden

Poster Group 2

Background incl. aims
Zeolites, characterized by their large and regular pores, are utilized to filter target molecules from mixtures, purify effluent by removing pollutants and in catalysis. Atomic resolution imaging of small molecules in pores will contribute to elucidate host-guest interactions between small molecules and porous structures and understand diverse molecular absorption/desorption behaviors in pores. Scanning transmission electron microscopy (STEM) is a powerful technique to capture interpretable atom-scale images, facilitating localized structural analyses. Recognizing the inherent sensitivity of zeolites and molecules to electron beam exposure, low electron dose imaging techniques, including the differential phase contrast (DPC) employing segmented detectors and 4D-STEM using pixelated detectors, have been developed. Pixelated detectors employed by 4D-STEM offer superior electron collection efficiency with fine resolution and high signal-to-noise ratio (SNR) at probe positions[1]. However, pixelated detectors entail higher costs and longer dwell time compared to segmented counterparts. The integrated DPC (iDPC) technique has shown its power in imaging light elements with low-dose conditions. Recently, a newly developed optimum bright-field (OBF) STEM technique demonstrates enhanced SNR relative to iDPC[2 3]. OBF images are reconstructed by combining the images captured by segmented detectors. Each segmented image is weighted by a frequency filter for the contribution to the Fourier component of the reconstructed OBF image, where the frequency filters are built using phase contrast transfer functions (PCTFs) for the segmented detector[2]. Here, the OBF-STEM technique with a custom-made python package is utilized for the efficient detection of molecules within the pores of ZSM-5 zeolite using a four-segmented detector.
Methods
The theoretical framework of the OBF STEM image can be derived from the single side band (SSB) ptychography[2], where the specimen is weakly electron scattering. The exit wave function M(k ,Q) is given by the convolution of the entrance probe wavefunction ψ(k)·ψ* (k-Q) on the specimen with the pupil function A(k) A* (k+Q) , where Q is the spatial frequency of the probe at spaced position r on the specimen in Fourier space. Therefore, the PCTF can be calculated by T* (k)T(k-Q)-T(k) T* (k+Q), where T(k) is the aperture transfer function defined as the multiplication of the aperture function with the probe wave function in reciprocal space. In a segmented detector, the STEM image intensity of the i-th segment I_i (r) is described mathematically as ∫I(k, r) D_i (k)𝑑k, where D_i (k) is the i-th segmented detector response function in reciprocal space and I(k, r) is the inverse Fourier transform of the diffraction pattern (|M(k, Q)|^2). The OBF STEM image is reconstructed by combining the segmented images weighted by frequency filters in reciprocal space, or combining the convolution of each segmented image with a corresponding point spread function (PSF) in real space[2]. For maximizing the SNR of the reconstructed OBF image, the PCTFs in the segmented detector are optimized by incorporating real-valued functions, such as high/low pass filters[2]. In this work, a custom-made python package is developed to calculate the PCTFs and the corresponding real-valued functions for OBF STEM image reconstruction. The specimen of ZSM-5 zeolite absorbed pollutants was imaged with the convergence semi-angle of 21 mrad on an aberration-corrected FEI Titan Cubed Themis Z microscope operated at 300 kV. A four-segmented detector was employed to capture

images using a beam current around 4.7 pA and a dwell time of 2 µs per pixel within a collection angle range of 8-42 mrad, with a camera length of 185 mm.

Results

The ZSM-5 with pollutants in pores was imaged along the [0 1 0] direction under a dose rate of 856 e-/Å². iDPC image (Figure a) and OBF image (Figure b) were reconstructed using the same dataset. Compared with the iDPC image, OBF image demonstrates clearer structural details due to its higher contrast and SNR, evident in line profiles and the cropped image (Figure d) from the same area in iDPC and OBF images. The superior contrast and finer resolution of OBF image enable more distinct observation of pollutants (marked by arrows in the line profiles) within pores than that of the iDPC image.

Conclusion

OBF-STEM images were reconstructed using the custom-made python package. This package implements algorithms to compute the PCTFs and the corresponding real-valued filters for image reconstruction. The reconstructed OBF image demonstrates enhanced contrast and SNR, giving clearer discernment of structural features. Importantly, features within the pores of ZSM-5 were distinctly distinguished in the OBF images compared to those reconstructed iDPC images. These findings imply that the OBF technique, employing a high-speed segmented detector, represents a promising approach for low-dose imaging of molecules encapsulated within the pores of zeolites.

A Better Insight Into Battery Materials Using A Correlative Approach

Dr Dan Haspel[1], Dr Joshua Lea[1], Dr Jonathan Moffat[1], Dr Pedro Machado[1], Dr James Sagar[1], Dr Louise Hughes[1]
[1]Oxford Instruments, High Wycombe, United Kingdom

IM-13 (2), Lecture Theater 5, august 27, 2024, 14:00 - 16:00

Continued demand for electrification of transport, portable consumer electronics and even grid level storage continues to drive rapid developments of battery technology. Although each use case has its own relative performance criteria there is an overall need to increase charge and power density, cell cycle lifetime and safety while continuing to decrease cost per cell. For NMC cathodes particle size and material consistency has a large impact on final cell performance. Material inconsistencies decrease lifetime and can even result in catastrophic failure. Rapidly determining consistency while performing detailed characterisation of identified irregularities enables significant improvements in the next generation of materials.
Here we show how using multiple techniques can deliver both that rapid assessment as well as detailed understanding of the material. However, it can be difficult and time consuming to know where on the sample to begin analysis. The first step is to create an overview of the sample, which can subsequently be used to identify areas for further analysis. A rapid (~2 min) survey using backscatter electron and x-ray (BEX) imaging identified areas of titanium (Ti) and sulphur (S). Where the chemistry was sufficiently divergent from NMC, that further analysis was required.
Once an interesting area with both Ti and S containing phases was selected, further detailed analysis was carried out. In this sample, it was the larger particles that were of interest to understand the chemical consistency. As some of the features identified in the BEX image were small and lithium is present, analysis at reduced electron energy (low kV) is preferred; firstly, to improve spatial resolution and surface sensitivity and secondly, to reduce beam damage of the sample. Windowless energy dispersive x-ray spectrometry (EDS) was used because the technique is designed for low kV analysis. Identifying molecules, particularly lithiated ones, is critical in beginning to understand the charging properties of the cathode. EDS is only sensitive to elements and not molecular structure, additionally Li can be difficult to detect using EDS in compounds, therefore Raman was used to identify lithiated and non-lithiated molecules. Raman can also be used to visualize where the molecules are within the NMC particles and characterise the degree of lithiation, which will dictate the electrical properties.
To understand the structure, texture and grain boundary information, which will also indicate the electrical properties and charging efficiencies, electron backscatter diffraction (EBSD) was carried out. In cathodes, grain boundaries are typically found to be a source of failure in large particles where electrolyte impregnation can cause cracking and degradation. To characterise how both structure and composition relate to the electrical properties of the cathode particles, Kelvin Probe Force Microscopy (KPFM), an electrical mode in atomic force microscopy (AFM), was used to measure localised electrical potential.
Fig.1 shows the complementary nature of individual techniques when spatially correlated. The Raman results showed that the Ti was associated with lithium titanate (LTO, teal) and the S was associated with a lithium sulphate compound (blue). The EDS was used to aid in identifying and qualifying the Raman spectra. Structurally it was found that a high percentage of the unit cells were aligning around the perimeter of the crystal. For optimum speed of charge and discharge it is preferable to align perpendicular in the 0001 direction with the particle radius, in this case it was

found to be perpendicular to the radius thus improving the motion of Li+ ions. The KPFM results showed that the small S area had a higher electrical potential than the surround particle. However, the larger S particle had zero electrical potential; this was because the S areas were damaged by the electron beam during EDS acquisition which caused bubbling of those areas, which would cause a hollow zone and would measure as zero. New regions containing S will be measured to correctly measure the electrical properties.
This work shows that a correlative workflow works well for battery cathodes and enables critical insights. Individually, the techniques deliver useful information that can help in understanding battery materials and improving processes. When the multiple techniques are correlated, they enable new conclusions, reduce uncertainty and in some cases stop the incorrect conclusion being drawn.

Quantification of Lithium in State-of-the-Art low Voltage STEM

Pr. Raynald Gauvin[1], Mr. Nicolas Brodusch[1], Mrs. Stéphanie Bessette[1]
[1]Mining and Materials Engineering,McGill University, Montréal, Canada

Poster Group 1

Background incl. aims
This paper will present new achievements and challenges in performing quantitative EDS and EELS maps of lithium-based materials in a state-of-the-art low-voltage scanning transmission electron microscope. With the energy revolution coming because of global warming, Lithium-Ion Batteries of higher energy densities and much lower cost must be developed to allow the transition of fuel-based vehicles to be replaced with electrical vehicles. This will only become a reality if we can quantify lithium at the Nanoscale to see where it becomes lost during the electrochemical cycling of the batteries.
Methods
State-of-the-art results acquired with the Hitachi SU-9000 dedicated STEM will be presented. This microscope has EELS capabilities that allow Li detection [1], being the first to be sold by Hitachi High-Technologies. It is also equipped with the Extreme EDS system from Oxford Instruments that can detect the K line of lithium [2]. The SU-9000 has a resolution of 0,22 nm in bright field STEM without aberration correctors and this allows lattice imaging. A cryogenic specimen holder allows to analyze Li based materials at 77 K.
Results
Figure 1-a shows an EELS spectrum of Li2FeSiO4 taken with the Hitachi SU-9000 at 30 keV. Even if X-ray emission was not detected with the EDS detector for this material for the same reasons stated above for Li2CoSiO4, the ionization edges are visible for Fe, Li, and Si. This shows the strong advantage of EELS over EDS (or WDS) for Li quantification. This is seen in figure 1-b which shows a Li EELS edge-to-background ratio map of an Al-Li 2099 alloy recorded with the three-detectors system on the Hitachi SU-9000 at 30 keV. This map shows the round δ' precipitates (Al3Li) of 5 to 20 nm and the T1 plates (AlCuLi) that have thicknesses between 1 to 2 nm. Results obtained with a cryo-holder to evaluate possible minimization of beam damage will be presented.
Conclusion
It is not always possible to detect Li with EDS because its 3S electron can be bonded with another atom. EELS is superior to EDS since it is always possible to detect the ionization edge if the beam damage can be minimized with a cryo-holder. The downside of EELS is the need for a transparent specimen.

Background
Liquid-phase transmission electron microscopy (LP-TEM) is an emerging experimental technique which permits the monitoring of processes in liquid samples with nanometer-scale resolution. Over recent years, LP-TEM setups have evolved into sophisticated model reactors for the study of physico-, bio- & electro-chemical processes propelled by the integration of various stimuli such as temperature, electric bias, and reaction media composition. In particular, microfluidic systems have inspired numerous expectations among the community, most notably the control of supply of reagents to and/or reliable removal of unwanted (radiolytic) species from the imaging region. However, the evolution of LP-TEM into a quantitative imaging technique remains limited by several issues, most of which are related to poor calibration of mass transport dynamics in the complex LP-TEM flow channel geometries.[1] Here, we will discuss fundamental aspects of mass transport in LP-TEM flow experiments.

Methods
A general approach combining experimental and theoretic methods for the calibration of mass transport in LP-TEM flow systems will be described.[2] The experimental part relies on image contrast variation achieved by flowing a contrast agent. The theoretic part relies on finite element modelling of relevant physics, i.e. convective and diffusive transport, in realistic 3D channel geometries. Both aspects will further be implemented in a rapid prototyping procedure for the fabrication of novel LP-TEM flow reactors: a virtual prototyping step that relies on an experimentally validated model is combined with a physical prototyping step that uses microfabrication routines (lithography and wet-etching). In addition, to study the impact of the established mass transport mechanisms on beam-induced chemistry, the finite element model is further extended by reaction kinetics of radiolysis.

Results & Discussion
A comprehensive understanding of mass transport phenomena in LP-TEM flow scenarios will be provided. First, the bimodal approach is applied to understand the hydrodynamic properties of different LP-TEM flow reactor geometries. In particular, crucial geometric features of the flow channels are identified that result in either convection or diffusion being the dominant transport mechanism.[2] Second, the effect of convective transport on radiolytic reaction networks will be investigated.[3] In contrast to established assumptions, only molecular radiolytic species can be rinsed effectively. In consequence, the concentration of highly reactive species (e.g. H* and e-) follow non-linear trends and increase with increasing flow velocity. The implications of these findings for

flow-based scavenging strategies will be highlighted. Thereupon, novel LP-TEM flow setups with diffusion-optimized mass transport properties, which exceed previous constraints by ~2 orders of magnitude, will be presented.[4] Finally, the benefits of the novel setups are demonstrated through different application examples from the field of materials reasearch and electrochemistry.[5]

We anticipate that the knowledge provided will enable better planning of in situ & in-operando experiments and support more reliable interpretation of results. The rational design of flow reactors will enhance correlatability to ex situ experiments and open new fields of LP-TEM research.

Background: Hepatitis E virus (HEV) is an burgeoning, zoonotic viral infection, and is the leading cause of acute hepatitis worldwide [1]. However, the lack of robust in vitro models supporting HEV infection [2] has hindered comprehensive studies on the various stages of viral infection and its impact on host cells [3].
Methods: CoCID [4] employs novel lab-scale Soft X-ray Microscopy (SXM) [5], a technology currently limited to select synchrotron facilities worldwide, enabling rapid, label-free imaging of whole, hydrated cells. We utilized model infection systems, including HEV genotype 1 and 3 replicon-transfected human hepatocytes, to investigate structural changes during infection. Additionally, we examined large, scaffold-free, polarized 3D spheroid models infected with clinical HEV to compare these pathological changes during full virus infection.
Results: Analysis of HEV replicon-transfected cells using SXM revealed a statistically significant increase in mitochondrial elongation. This observation was corroborated by light and electron microscopy techniques. Furthermore, examination of 3D spheroid models infected with clinical HEV demonstrated notable structural changes, which were explored using Correlative Electron-Soft X-ray Microscopy (CEXM) and Correlative Light-Electron microscopy (CLEM).
Conclusions: Our study demonstrates the utility of SXM and correlative approaches in elucidating the dynamics of HEV infection. The observed structural changes in infected cells provide further understanding of HEV biology and may inform the development of targeted therapeutic interventions against HEV. Moreover, the development of a Correlative Light-Electron-Soft X-ray Microscopy (CLEXM) workflow enhances our capability to investigate viral pathogenesis.

Poster Group 1

In recent years, there has been a remarkable increase in interest in ruthenium-based transition metal compounds, especially in the fields of quantum materials and strongly correlated electron systems. The reason for this is their moderate spin-orbit coupling, which is neither too weak nor too strong compared to the Coulomb interaction U. Due to this property, the relatively heavy 4d transition metal ruthenates exhibit a number of unusual properties compared to 3d transition metals. These include unconventional superconductivity, metal-insulator transitions, high-temperature ferromagnetism, Haldane chains, and orbital ordering. The interplay between localized and itinerant electrons, together with the orbital degrees of freedom in ruthenate systems, contributes to a wider range of electronic and magnetic properties [1, 2]. Given this potential of Na-Ru-O systems to serve as a promising model for the study of electron correlations in mixed-valence 4d systems, research in this area remains surprisingly limited.

$NaRu_2O_4$ exhibits an atypical metal-to-metal phase transition with emergent charge order (CO) [3]. Typically, a CO state, dominated by the inter-site energy U, tends to confine charge carriers to specific atomic positions, resulting in an insulating phase. Therefore, metallic behavior and charge ordering are generally considered to be mutually exclusive. Through single-crystal X-ray diffraction and theoretical studies, an unconventional type of bonding has been revealed in metallic $NaRu_2O_4$, involving an additional ordering of Ru3+/Ru4+ species. Below the critical temperature (TC = 535 K), a structural transition occurs from the high-temperature (HT) phase with the space group Pnma to the low-temperature (LT) phase with emergent superlattice reflections (0, ½, 0), which cannot be explained by the Pnma space group. Instead, the structure undergoes a transformation with a doubling of the unit-cell size and the formation of Ru-Ru metal dimers through orbital-driven Peierls dimerization. The final LT crystal structure of $NaRu_2O_4$ exhibits monoclinic symmetry with the space group P1121/a. Remarkably, short Ru-Ru dimers (bond-centered charge density wave) with direct metal-metal bonding coexist with metallic conductivity [3].

This study focuses on the investigation of the atomic-scale lattice reconstruction in the metallic $NaRu_2O_4$ system. High-angle annular dark-field scanning transmission electron microscopy (HAADF STEM) with atomic-resolution and electron diffraction techniques are used to reveal the structural transition with temperature, confirming the occurrence of orbital-driven Peierls dimerization as the sample temperature drops below TC. Periodic lattice displacement (PLD) maps further visualize the atomic displacement along different zone axes. The combination of (in-situ) HAADF STEM and Fourier processing allows for the mapping of phase transitions with complex displacement patterns in the picometer range, providing direct evidence for the bonding order in metallic $NaRu_2O_4$ (Figure 1).

Delafossites are classified as oxides with a general chemical composition of ABO_2, containing metal ions in the formal oxidation states of A+ and B3+ [1]. Depending on the cations of choice, delafossites exhibit a wide range of interesting physical properties, including p-type or bipolar semiconductivity (when A = Cu, B = Al, Cr, Fe, Ga, Y, In), photocatalytic activity (as observed in $AgGaO_2$), and metallic conductivity ($PdCoO_2$, $PdCrO_2$, $PdRhO_2$, $PtCoO_2$, and $AgNiO_2$) [2].

The metallic delafossites crystallize in the rhombohedral 3R phase with $R\bar{3}m$ symmetry and exhibit unusually large in-plane conductivities for oxides, surpassing even most pure metals. For example, $PdCoO_2$ has a conductivity about four times that of pure Pd, approaching the level of pure Cu, Ag, and Au. Therefore, metallic delafossites such as $PdCoO_2$ are of great interest for exploring their potential in oxide heterostructures and for applications in electronics and spintronics. To account for the limited size of their single crystals, researchers have fabricated thin films of metallic delafossites using methods such as reactive sputtering, pulsed laser deposition (PLD), and molecular beam epitaxy (MBE) [2]. Delafossite thin films are typically grown along the c-axis on substrates such as Al_2O_3 (0001) and β-Ga_2O_3 (201). Despite significant lattice mismatches between metallic delafossites and substrates, e.g., a mismatch of ~6% for $PdCrO_2$ on c-Al_2O_3, high-quality c-axis oriented thin films can be successfully grown. This is possible due to an intriguing mechanism during the growth process that appears to mitigate the mismatch strain at the interface, although the exact nature of this mechanism remains unexplained. In particular, the realization of high-quality films can be attributed to the choice of CoO_2 as the first layer grown in ozone-assisted MBE [3,4].

In this study, we reveal the presence of atomic-scale reconstructions at the $PdCoO_2$ – Al_2O_3 interface by combining advanced scanning transmission electron microscopy (STEM) techniques, including electron energy loss spectroscopy (EELS) and 4D STEM phase reconstructions via electron ptychography. The reconstructed phase (Figure 1(a)) reveals the presence of atomic columns at the interface that are not consistent with the atomic model of either the film or the substrate, while EELS fine structure analyses (Figure 1(b)) indicate a Co valence reduction across the interface. Insights from the combination of spectroscopy and phase reconstruction suggest the formation of a unit-cell thick layer of CoO within the first atomic layer of the substrate. This previously undiscovered behavior has significant implications for the understanding of the mechanism of epitaxial growth of metallic delafossite thin films.

FFT denoising methodology through CNN for the study of WS2 vacancies

Ivan Pinto[1], Mr. Marc Botifoll[1], Mr. Yuki Wang[3], Pf. Chen Wang[3], Pf. Jordi Arbiol[1,2]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Barcelona, Spain, [2]ICREA, Pg. Lluis Companys 23, Barcelona, Spain, [3]MSE, Tsinghua University, Beijing, China

2D materials as WS2 have become increasingly relevant and widely studied in recent years due to their electronic and optical applications [1]. One of the most effective techniques for characterizing these materials and studying their physical properties is High-Angle Annular Dark-Field (HAADF) imaging in a Scanning Transmission Electron Microscope (STEM). On the other hand, to study lighter atoms it is common to use Integrated Differential Phase Contrast (iDPC) STEM. These techniques allow researchers to study the crystallography of the material to determine the presence of defects. These images often contain noise that poses a challenge when studying vacancies. Consequently, we developed an FFT denoising technique employing a Convolutional Neural Network (CNN) with a U-NET architecture [2, 3]. The CNN was trained using more than 5000 simulated spectra from diverse materials and various orientations. After FFT denoising, we could perform an inverse FFT (IFFT) to return to real space. This results in a significantly cleaner image, rendering crystallographic analysis more accessible, as atomic positions become much more discernible. Conversely, the FFT denoising method leads to the emergence of ‘fake atoms' in locations where vacancies should exist. While this outcome may initially appear counterproductive, it was, in fact, the crucial element that enabled the execution of this study. In this way, by subtracting the original experimental HAADF-STEM image from the filtered one, we obtain a new images where the bright spots correspond to the atomic vacancies
(Figure 1).
In conclusion, the methodology employed in this study has enabled a statistically significant analysis of vacancies across multiple images. Each image has been subjected to a detailed examination of more than 3000 atomic positions, yielding robust and reliable results. This approach not only provides a profound understanding of vacancy distribution but also gives the way for automating the statistical analysis of vast amounts of images within short timeframes. This potential for automation not only enhances process efficiency but also holds promise for accelerating the pace of discovery and understanding in research fields reliant on atomic-scale image analysis.

Poster Group 1

Background incl. aims:
Plasmas, sometimes called the fourth state of matter and defined as an ionized gas, have applications in a variety of fields, including biomedicine, materials science, and gas conversion. A typical example of plasma technology is their use in the semiconductor industry, where they fulfill a critical role in the etching process of silicon wafers when fabricating nano-scale components that make up computer chips [1]. At the same time, plasmas are heavily researched to gain further fundamental insights, and to develop novel technologies and applications. These research areas include plasma catalysis, gas conversion, nanomaterial synthesis, and biological treatments [2].
Many of the relevant plasma processes take place at a microscopic scale. However, current diagnostics (e.g., optical techniques) are often limited to global measurements, naturally averaging out microscopic effects. Micro-scale investigations of plasma-treated materials are typically limited to ex situ studies, where post-mortem analyses are performed on samples after plasma treatment [3]. This limits the temporal resolution of current studies, while also exposing the sample to ambient conditions during the transfer from the plasma device to the diagnostic equipment.
Therefore, we aimed to develop a setup that enables the formation of a plasma inside a scanning electron microscope (SEM). Specifically, we sought to achieve true in situ SEM imaging during plasma operation and to investigate the effect of plasma on materials at high spatial and temporal resolution, while preserving the original state of the plasma-treated sample.
Methods:
We modified an environmental SEM to integrate the instrumentation for generating and monitoring a plasma within the chamber [4]. A custom flange was designed to provide a passthrough for electronics and gas supply. The gas supply is connected to a steel tube with a small orifice, which brings the gas close to the sample, and they are both placed in the field of view of the SEM. The sample is grounded, while the nozzle is connected to a DC-DC converter placed inside the chamber which is powered by a DC power supply outside of the microscope. This way, plasmas in a variety of gases were generated by supplying the nozzle with a voltage up to 2 kV. The current flowing through the sample to the ground was measured using a shunt resistor, enabling real-time monitoring of the plasma discharge. While the plasma was on, the SEM could be used in its normal high-vacuum operating mode.
The in situ setup was tested for a range of plasma and imaging conditions. Different discharge gases were used to generate the plasma, including N2, CO2, and an O2/Ar mixture. Flow rates were varied between 2.5 and 7.5 sccm, which was monitored by a mass flow meter outside of the microscope. Further, the distance between the nozzle and the sample could be varied, typically between 75 and 150 µm. This setup offers high flexibility, though a plasma discharge was not possible for all conditions (e.g., large gap distance and low flow rate) at our maximum applied voltage of 2 kV. True in situ imaging was possible with both the secondary electron and backscattered electron mode of

the Everhart-Thornley detector, while EDX measurements were performed between plasma treatments.

Results:

To characterize the plasma discharge, we acquired the voltage-current characteristics, where the plasma current was monitored while varying the applied voltage. These data were obtained for a number of gap distances and gas flow rates. These characteristics all exhibit a rising slope and the positions of the curves for varying conditions are indicative of a so-called obstructed abnormal glow discharge. This implies that a discharge should be sustainable at even lower voltages, if the gas density could be increased.

Next, we investigated how the plasma operation affected SEM imaging, showing that true in situ SEM imaging was possible during the plasma discharge. While the electron beam is deflected by the electric field needed to sustain the plasma, the presented setup is sufficiently stable to obtain high-quality SEM images. The deformation of the images by the deflected electron beam must be considered for quantitative image analysis, but regardless the images are suited for qualitative studies. In a proof-of-concept example, a video was captured where the sputtering of the sample could be monitored in real-time. The homogeneous sputtering of the sample also yielded microscopic conical structures, formed out of spherical particles or impurities that were present on the sample surface.

To further explore the SEM-plasma synergy, we employed elemental mapping to study the composition of the sample and how it is affected by various plasmas. Apart from the physical effects of the plasma (i.e., sputtering), chemical reactions were also observed. We showed that oxygen-containing plasmas, e.g., CO_2, can oxidize the Cu sample outside of the sputtered area. For the latter, the sputtering effect was dominant and exposed the pristine Cu below the surface.

Finally, we explored the effect of the voltage polarity on the plasma properties, since a negatively biased electrode accelerates the positive ions to the nozzle rather than to the sample. This yielded sputtering of the nozzle instead of the sample and subsequent redeposition of nozzle material on the sample. At the same time, the sputtering of the sample was strongly limited while the oxidation in a CO_2 plasma could be observed for a broad region.

Conclusions:

This work presents a dedicated setup to generate a plasma inside a scanning electron microscope. The setup enables true in situ SEM imaging, where electron-based images can be acquired while treating the sample with a plasma. The interaction of the plasma and the sample was studied by real-time imaging, where a pit being formed in the sample sheds light on the sputtering behavior of the setup. Moreover, microscopic conical structures were formed by bombarding spherical particles or impurities with ions. Finally, chemical effects of the plasma were observed, where a CO_2 plasma was able to oxidize the Cu sample. This setup is a stepping stone for future research, both in the direction of materials science and toward more advanced plasma diagnostics.

Localization techniques in biomedical electron microscopy: good as gold

Wiebke Möbius[1]
[1]Max-Planck-Institute for Multidisciplinary Sciences, Göttingen, Germany

LS-05, Lecture Theater 5, august 26, 2024, 14:00 - 15:00

Background
Combining structural information with the localization of molecules and proteins provides important information for the investigation of cellular processes especially in the context of pathology. Different strategies are available to obtain samples suitable for labeling techniques in electron microscopy.
Methods
In principle, labeling probes can be applied to a permeabilized sample before embedding and sectioning, called preembedding-labeling. Alternatively, the probes are used to localize molecules on the section by so-called post-embedding or on-section labeling. A popular example for this approach is immunolabeling of cryosections according to Tokuyasu. Apart from this, other methods are available to gain accessibility for probes to subcellular structures such as whole mount or freeze fracture replica labeling.
Results
By using mostly cryosections according to Tokuyasu we studied lipid and protein distribution in cells and tissues investigating for example the formation and composition of exosomes secreted by cultured B-cells as a mechanism of antigen presentation. Exosomes also play important roles in cell-cell communication within the nervous system. We showed that exosomes are involved in axonal support by glia cells such as oligodendrocytes which is the myelin forming cell type in the central nervous system. These properties were affected by deficiency of oligodendrocytes for specific myelin proteins. We show examples how immunoelectron microscopy provided important data complementing other investigation methods in understanding cell biology in general and axo-glia interaction in particular.
Conclusion
Different approaches for sample preparation and the different strategies in immunoelectron microscopy are available. Which of those is applied depends on the question under investigation and the properties of the sample. These techniques allow the localization of proteins or molecules in the context of the cellular or tissue environment. Localization probes require a careful validation of their specificity.

Alternating-probe electron ptychography

Meng Zhao[1], Mr. Anton Gladyshev[1], Prof. Christoph Koch[1]
[1]Humboldt University of Berlin & Center for the Science of Materials Berlin,, Berlin, Germany

IM-03 (2), Plenary, august 28, 2024, 14:00 - 16:00

Background:
Ptychography has recently become a very powerful phase retrieval method and has been investigated by a number of groups in recent years. While applying a higher dose and a perfect electron microscope seems intuitively advantageous for maximizing the precision with which the unknown parameters can be determined in this process, the reality is constrained by various limitations. Different applications are required to push their limits in different aspects; there is still quite some potential for further optimization. Much effort has been directed towards refining physical models to incorporate more prior knowledge into reconstruction algorithms, such as adding different constraints [1], using multi-probe illumination to model partial coherence [2], and using mixed objects to model lattice vibrations [3].
Recent advances in the development of a low-noise, fast-response phase plate [4] present novel opportunities for adopting a different approach to increasing the number of known parameters in the reconstruction. Probe-diverse ptychography has been proven to be capable of overcoming the problem of converging to local minima inherent in the standard single probe scheme [5]. Initial tests in X-ray ptychography came to the conclusion that two different probes would be sufficient. In this abstract, we demonstrate, using simulated data, the use of a phase plate that adds different phase shifts to the probe at different scan positions. During reconstructions, we initialize and reconstruct a single probe, but incorporate an additional step within the algorithm to introduce phase changes to the wavefront that are induced by the phase plate.
Methods:
As a proof of principle for probe-diverse ptychography, we simulated 4D-STEM data of two hexagonal boron nitride (h-BN) crystals stacked with a 10° rotation between them (see Figure, (a)-(c))). (a) represents the projected potential of the complete sample, (b) shows the projected potential of the top half of the sample with no rotation, (c) depicts the projected potential of the second half of the sample with a rotation of 10°. For different electron doses, we simulated three distinct sets of data, each generated independently. These sets include data obtained from a probe without phase shift, a vortex beam, and a beam with phase shift of π applied to half of the elements of the phase plate [4]. The simulations were all conducted with a defocus of 9 nm, a scan step of 1 Å, and partial coherence implemented by convolving the 4D-STEM data set by a Gaussian with a full-width at half maximum (FWHM) of 0.7 Å. Subsequently, we generated two additional data sets. The first combined subsets of data were obtained from the normal probe and the vortex probe. The second data set combined data from all three previously mentioned sets. These simulations aimed to evaluate the effectiveness of probe-diverse ptychography in reconstructing the sample's structure with enhanced accuracy and resolution.
We performed reconstructions of all six simulated data sets using a multi-probe approach [2]. To estimate the quality of the reconstructions, we employed the Structural Similarity Index (SSIM) between the reconstructed phase object and the original potential utilized to generate the data.
Results:
In Figure(d)-(f), SSIM versus dose for different probe configurations is presented. (d) shows the sum of the SSIM of all reconstructed slices, reflecting the fidelity of the reconstruction for the entire

structure. This plot indicates that reconstructions in extremely low-dose scenarios are not entirely successful, with relatively low SSIM values. In these cases, the benefit derived from applying diverse probes is overshadowed by noise. Upon reaching a moderate dose range (from 1×10^4 e/Å^2), despite the larger probe size associated with the vortex and pi beams, probe-diverse ptychography still yields superior reconstructions. Additionally, the dataset comprising three distinct probe configurations exhibits further enhancement. (e) shows the sum of the SSIM for the first half of the potential slices, and similarly, (f) shows the sum of the SSIM for its second half. These results reveal that the reconstruction from the dataset containing three different probes captures more detailed information along the z-axis, especially at high doses.

Conclusions:

In this abstract, we have demonstrated a novel approach to diverse-probe ptychography and provided a proof of principle for its effectiveness in electron ptychography. Our findings suggest that applying more than two probes in ptychography leads to further enhancements in reconstruction quality. Additionally, the modification of the probe is not limited to phase plate adjustments. It's worth mentioning that the aberration corrector can also achieve similar outcomes, albeit with a limited number of configurable parameters.

The effect of fragrance molecules on surfactant self-aggregation in aqueous solutions studied by cryo-TEM

Sapir Lifshiz-Simon[1], Prof. Yeshayahu Talmon[1]
[1]Department of Chemical Engineering and the Russell Berrie Nanotechnology Institute (RBNI), Technion – Israel Institute of Technology, Haifa, Israel

Poster Group 2

Background:
The interaction of ions and hydrophobic additives with charged surfactants is a fundamental phenomenon in colloid science. This phenomenon sets the basis for industrial formulations of surfactant-based products with the addition of minor components, such as salts and fragrances, in personal care and cosmetics formulations. Although such formulations are used daily worldwide, and studies report that minor components significantly modify the surfactant nanostructure and properties, little is known about their exact effects on surfactant self-aggregation at the nanometric scale. Our research aims to elucidate the effects of additives on the self-assembled nanostructure of surfactants, thereby, serving as a basis for optimized formulations of surfactant-based products.
Methods:
We study the nanoaggregation of a surfactant system with additives by cryogenic transmission electron microscopy (cryo-TEM), a direct-imaging advanced technique, combined with careful specimen preparation to avoid nanostructural changes caused by shear. For imaging, we use the Volta phase plate (VPP) to enhance image contrast. To complement our imaging, we conduct rheological measurements to predict nanostructural changes, as the viscosity is strongly affected by the self-aggregated nanostructure of the system. The surfactant model system we use in our research is sodium laurylethersulfate (SLES), an important and widely used surfactant ("detergent") that is usually accompanied by other components, such as salts and fragrances. We study how the nanostructure of SLES aggregates changes, and thereby, their macroscopic behavior, when adding different salts (LiCl, NaCl, KCl, and CsCl) and fragrances (vanillin, limonene, citronellol, and linalool). We study the system at different salt-to-surfactant molar ratios (X).
Results:
In our study, we show the correlation between the rheological properties and the nanostructural changes of SLES with varying salt concentrations [1], and in the presence of fragrance molecules (Figure 1, showing 5 wt.% SLES with NaCl and 1 wt.% limonene, changing the nanostructures from short to elongated thread-like micelles (TLMs) to vesicles). Each additive slightly changes the zero-shear viscosity peak in terms of viscosity value and the salt concentration required to reach its maximum value. Moreover, we present the formation of different nanostructures and coexisting pseudo-phases when different types of components are added. In our recently published paper [1], we showed the above-mentioned effects on SLES in the presence of different salts, while here, we describe the extension of this study to the addition of fragrance molecules. We also demonstrate how the specimen preparation process affects the imaged nanostructures through the formation of artifacts caused by the shear of blotting during cryo-TEM specimen preparation [2].
Conclusion:
To obtain a comprehensive picture of the effects of different components on SLES, we combine rheological measurements for predicting the zero-shear viscosity peak, followed by cryo-TEM direct imaging. Salts affect the nanostructure through ion effects related to their size and affinity, while the addition of fragrances affects through complex mechanisms. Cryo-TEM is a well-suited tool to explain

and distinguish tiny differences in these systems and should be performed on a carefully prepared specimen with sufficient on-the-grid relaxation and minimal shear during blotting.

In-Situ TEM assessment of phase transformation in VO2-based thin films with Ho addition

Ellen Suhr[1], Dr. Aleksander Kostka[2], Prof. Dr.-Ing. Alfred Ludwig[1]
[1]Institute for Materials, Ruhr University Bochum (RUB), , Bochum, Germany, [2]ZGH, Ruhr University Bochum (RUB), , Bochum, Germany

Poster Group 2

Background incl. aims
We present the fabrication and characterization of VO2-based thin films with Ho addition. The thin films were prepared as so-called materials libraries by reactive co-sputtering from two targets (V, Ho) to achieve a composition gradient. The effect of Ho on the phase transformation and its functional properties, like the thermochromic effect, has not been studied yet, and the materials libraries enable a screening of a large composition spread in relatively short time. The materials libraries were characterized in a high-throughput approach regarding their chemical composition, crystallinity, and electrical resistance at different temperatures to study the phase transformation. TEM investigations were carried out on two types of samples, both selected from specific composition region of the materials library: (i) focused ion beam (FIB) prepared TEM lamella, for analysis of the present Ho-rich precipitates, and (ii) sputtered on SiN Wildfire (DENSsolution) chips for in-situ TEM heating experiments to assess the phase transformation – to avoid Ga-ion contamination and its effects on the phase transformation.[1]
Methods
The thin films were prepared by reactive co-sputtering on 4-inch Si wafer and the Wildfire chips from two targets: V and Ho2O3. The positioning of the targets results in two gradients across the thin film library (see Figure 1) the composition gradient along the diagonal from lower right to upper left with decreasing Ho-content, and a thickness gradient along the other diagonal. The substrates were heated to 500 °C and the oxygen flow was controlled using plasma emission monitoring.[2] The thin film thickness was controlled by the deposition time: 30 min (approx. 150 to 350 nm) for the materials library on Si (SEM, EDS, XRD, resistance measurements) and 5 min for the depositions on the Wildfire chips (approx. 40 nm).
Results
The materials library was first characterized regarding its chemical composition (EDS), crystallinity (XRD, Figure 2) and electrical resistance (in the range of 20 to 120 °C, Figure 4) getting the first overview of the thin films properties using high-throughput automated measurements.[3]
The preliminary investigations of the library suggested a single-phase solid solution with a monoclinic VO2 phase. The temperature-dependent resistance measurements reveal a slight shift of the transformation temperature towards lower temperatures with increasing Ho content (Figure 4).
TEM analysis of the selected composition region revealed the presence of small Ho-rich precipitates and larger VO2 crystals. The in-situ heating experiments showed that the phase transformation starts at 54 °C and it is completed at about 60 °C. The transformation is well visible in the electron diffraction but does not result in microstructural changes; grain size and morphology remain unchanged.
Future work shall focus on the investigation of the thin films functional properties and their possible applications in nanoactuators or in thermochromic coatings for windows.

SEMNet: Deep Synthetic Training for Unprecedented SEM Image Denoising and Super-Resolution

Junghun Cha[1], Ph.D Doohyun Cho[1], Ph.D SeungJae Lee[1]
[1]D.notitia Inc., Seoul, Republic of Korea

IM-10 (3), Lecture Theater 5, august 30, 2024, 14:00 - 16:00

The Scanning Electron Microscope (SEM), an essential tool in electron microscopy, excels in delivering detailed visuals by directing an electron beam over a specimen's surface. Its widespread use in material science, biology, and various industrial fields stems from its ability to provide high-resolution, in-depth focus, and three-dimensional imagery.

Despite these advantages, acquiring high-quality SEM images can be challenging. This is due to inherent resolution limitations and noise factors that impair image clarity. Addressing these issues, our study introduces a method to enhance SEM image quality through advanced deep-learning algorithms, focusing on both denoising and super-resolution (SR) to refine image details and clarity effectively.

We introduce SEMNet, a Convolutional Neural Network (CNN) specifically designed for SEM image restoration with an upscale factor of 2. Inspired by the successes of the RRDBNet [1] in real-world image restoration, our model innovatively applies this architecture to SEM imagery, overcoming typical denoising and SR challenges. Fig. 1 illustrates our SEMNet.

SEMNet's core consists of 6 Residual-in-Residual Dense Blocks (RRDBs), a sophisticated structure pivotal for meticulously refining image details. Within each RRDB, we embed 3 Residual Dense Blocks (RDBs) characterized by their densely connected convolutional layers (denoted as Conv in Fig. 1). This design ensures a seamless flow of data and gradients throughout the network, significantly boosting feature extraction performance. The RDBs each consist of 5 convolutional layers paired with LeakyReLU activation functions (denoted as LeakyReLU in Fig. 1), having a negative slope coefficient of 0.2. Overall, SEMNet comprises 94 convolutional layers and 19 LeakyReLU activation functions, considering the additional convolutional layers outside the RRDBs as well. The network concludes with an up-sampling convolutional layer (denoted as Upsample in Fig. 1) that utilizes nearest neighbor interpolation to achieve SR, enhancing the quality and resolution of SEM images.

To effectively tackle the challenges posed by diverse noise types and low-resolution issues in SEM images, we devise a degradation modeling strategy specialized to producing synthesized low-quality (LQ) images from high-quality (HQ) counterparts. Specifically, our methodology concentrates on simulating two primary noise types frequently observed in SEM images: Gaussian noise, with a mean of 0 and a standard deviation ranging from 2 to 25, and Poisson noise, with a lambda value (λ) between 10^2 and 10^4. Moreover, we integrated additional degradations into our datasets, such as Gaussian blurring effects and up-downscaling processes. This comprehensive approach is designed to bolster the robustness of our SEM image restoration model by broadening its exposure to a variety of noise and other degradation scenarios. Note that it serves as a form of data augmentation, dedicately aimed at enhancing image restoration performance.

We trained the model for 5.44×10^5 iterations using Adam optimizer, with a batch size of 4. The learning rate starts at 0.0001 and is halved when the iteration reaches a multiple of 2.0×10^5. The training utilizes the following loss functions with respective weights: L1 loss (1.0), Histogram loss [2] (0.1), and Total Variation loss (0.01). The L1 loss effectively minimizes absolute pixel differences, playing a crucial role in image restoration. Histogram loss targets the reduction of pixel distribution disparities, ensuring the restored image faithfully mirrors the statistical characteristics of the original.

Total Variation loss focuses on diminishing noise and maintaining fine details, like edges, enhancing the overall quality of restored images. Our model is trained with 1300 real SEM images and 1300 images sampled from Flickr2K [3], which is the public dataset that has high-resolution real-world images from multiple categories such as nature, cityscape, human, animal, etc.

To quantitatively evaluate the performance of SEM image SR, we employ two metrics: Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM). PSNR measures the pixel-level accuracy between the reconstructed and the original images, while SSIM assesses the perceptual quality by considering changes in luminance, contrast, and structural similarity. For both metrics, higher values indicate better performance. A testing set of 25 SEM images was used to calculate both metrics.

Compared to the classical restoration using bicubic interpolation (for SR) and Gaussian blurring (for denoising), SEMNet achieved an increase of 0.212dB in average PSNR and 0.1379 in average SSIM. These results suggest that deep learning-based image restoration methods surpass classical image processing techniques in enhancing the quality of SEM images. Fig.2 shows the qualitative results of classical restoration and the SEMNet. The original sizes of the LQ and HQ images are 640×480 and 1280×960, respectively. Our SEMNet demonstrates superior visual performance compared to the classical restoration method.

In conclusion, we introduce SEMNet, a new deep-learning model for restoring LQ SEM images to HQ ones. With a diverse training dataset, SEMNet effectively removes multiple types of noises and upscales the image resolution through detailed degradation modeling and specialized loss functions. It surpasses classical restoration methods in improving SEM image quality, both quantitatively and qualitatively. Our work will contribute to the field of microscopy image restoration by introducing innovative deep-learning architecture designs and training strategies, specifically tailored to handle highly complex and diverse degradations in SEM images.

Deep learning 3D-mineral liberation analysis with micro-X-ray fluorescence, micro-computed tomography, and deep learning segmentation

Dr. Patrick Tung[1,2], Amalia Halim[1], Dr. Helen Wang[1], Dr. Anne Rich[1], Dr. Xiao Chen[3], Prof. Klaus Regenauer-Lieb[4], Dr. Christopher Marjo[1]
[1]Mark Wainwright Analytical Centre (MWAC), University of New South Wales, UNSW Sydney, Australia, [2]Research Technology Services, University of New South Wales, UNSW Sydney, Australia, [3]Mineral Resources, Commonwealth Scientific and Industrial Research Organisation (CSIRO), Kensington, Australia, [4]WA School of Mines: Minerals, Energy and Chemical Engineering, Australian Resources Research Centre (ARRC), Curtin University, Kensington, Australia

Poster Group 2

Backgrounds
Mineral liberation has become a key step in the mineral processing industry to quantitatively determine the volume fraction of valuable commodities. Several semi-automated techniques, such as backscattered electron (BSE) images with energy-dispersive spectroscopy (EDS) marketed as commercial systems such as QEMSCAN have been developed for this purpose. However, the extrapolation of the collected 2D data to 3D volumetric remains problematic. Recent developments in X-ray microcomputed tomography (µCT) made it possible to non-destructively characterise these minerals. The problem is the densities of some geomaterials are similar, hence without additional information, it is difficult and often impossible to reliably differentiate the phases just based on µCT data. In this study, we combined the micro-X-ray fluorescence (µXRF) with µCT data and develop a workflow incorporating statistical analysis and deep learning segmentation to interpolate the 2D data into 3D volume (Deep-XFCT).

Methods
The rock used in this study was a fine-grained 24 mm basaltic andesite sample that has a clear and distinct mineral inclusion. A combination of analytical techniques was used for the mineral analysis, which include (1) XRD on powder sample to understand the mineral presence and their abundance, (2) µCT to get 3D volumetric data, (3) µXRF to get elemental mapping for the mineral labels and atomic mass percentages of discrete points for mineral verifications, (4) Raman Spectroscopy to cross check the mineral identifications through µXRF data. The data processing was performed in two steps: (1) establishing ground truth labelling of the mineral phases through µXRF elemental mapping using K-mean clustering, (2) use of the ground truth labelling to train a deep learning model that will segment the mineral phases in 3D µCT data with a specific convolutional neural network architecture specifically designed for image segmentation (U-Net model) using two commercial software Dragonfly ORS and Avizo.

Results
The XRD results provided three prerequisite information for the workflow. First, the mineral phases that exist within the sample that holds important elemental information to correlate with the µXRF data. Second, the number of mineral phases that was presence, which guided the number of clusters for the K-mean clustering. Third, the mineral phases percentage abundance which were used as the validation for the cross-referencing with the K-means clustering abundances and the accuracy of segmentation from the deep learning.

The XRD shows the presence of albite, ankerite, clinochlore, illite, laumontite and quartz. By applying the geochemical principles to the K-means clustering centroids of the µXRF maps, illite, ankerite, and clinochlore can be unambiguously identified through the highest elements concentration present in each mineral. Quartz and albite were identified through the µXRF point analysis by the highest Si and Na mass percentage, respectively. Laumontite did not have a unique elemental identifier nor characteristic combination of elements and was identified by deduction as the final element. Raman Spectroscopy was able to confirm the presence of albite, clinochlore and quartz.
The minerals assigned to each pixel of the µCT orthoslice on the top and bottom surface of the sample where a U-Net neural network model was trained to segment the µCT based on the mineral labels. From visual analysis, the model captured the major contours of the mineral phases. This includes separating the albite and illite matrix to a good approximation, despite their identical grayscale value. However, the model failed to recognise the finer details apparent in the labelled training data. The overall accuracy from all minerals for top and bottom surfaces from the U-Net model in Dragonfly ORS 2021.2 were 70.23% and 69.56%, respectively. Furthermore, the results from the U-Net model in Avizo 2021.1 were similar with 73.57% and 72.08% for the top and the bottom surfaces. To validate the segmentation from the model, the sample was cut 5mm from the top and bottom of the plug and the surfaces were subsequently mapped with µXRF to allow the mineral phases maps within the volume of the sample to be compared. In comparison to the training data, the validation data has lower but serviceable accuracy. Using the phase identification as labels, a neural network was successfully trained to segment other slices throughout the volume to obtain a 3D representation of the mineral phases in the sample.

Conclusions
Our results successfully demonstrate semi-automated multi-modal analysis with an approach that is universal to any multi-instrument approach. The blend of µXRF and µCT provides a unique opportunity for robust 3D mineral liberation analysis in both field and laboratory applications when combined with Deep-XFCT. While Deep-XFCT did not provide pixel-level accurate segmentation, it was able to provide an excellent proxy for the purposes of obtaining the presence, location, distribution, and morphology of grains dispersed throughout a core plug. It was also shown that Deep-XFCT was able to differentiate fine-grained minerals of similar density that would be impossible by manual segmentation. This technique is a valuable technique that has the potential to expedite 3D mineral liberation analysis.

Solving the controversy of the metal-insulator phase transition in chromium nitride thin films

Magnus Garbrecht[1], Ms Ashalatha Indiradevi Kamalasanan Pillai[1], Mr Bidesh Biswas[2], Mr Bivas Saha[2]
[1]The University of Sydney, Sydney, Australia, [2]Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, India

PS-02 (1), Lecture Theater 5, august 28, 2024, 10:30 - 12:30

Background incl. aims
CrN is a hard coating material that has applications in abrasion and wear-resistant cutting tools, bearings, and tribology applications due to its high hardness, high-temperature stability, and corrosion-resistant properties. Recently, CrN has also attracted significant interest due to its high thermoelectric power factor [1]. Much of debate in the literature is around CrN's unique and intriguing metal-insulator phase transition. While CrN bulk single-crystals exhibit the characteristic metal-insulator transition accompanied with structural (orthorhombic-to-rocksalt) and magnetic (antiferromagnetic-to-paramagnetic) transition at ~260 - 280 K, observation of such phase transition in thin-film CrN has been scarce, and the exact cause of the absence of the transition in several thin film studies is not well-understood [2].
Methods
STEM images and EDS maps were recorded with an image- and probe-corrected and monochromated Themis-Z 60-300 kV equipped with a high-brightness XFEG source and Super-X EDS detector system for ultra-high-count rates, operated at 300 kV. The spatial resolution in STEM mode was 0.7 Å. EDS maps used for atomic % quantification have well above 1 M counts, and k-factor analysis and absorption-corrected background subtraction were employed.
Results
Here, we demonstrate that the formation of a secondary metallic Cr2N phase during the growth inhibits the observation of metal-insulator phase transition in CrN thin films, see Figure 1. When the Cr-flux during deposition is reduced below a critical limit, an epitaxial and stoichiometric CrN thin film is obtained that reproducibly exhibits the phase transition. Annealing of the mixed-phase film inside reducing NH3 environment converts the Cr2N into CrN as revealed by HRSTEM imaging and EDS mapping, and a discontinuity in the electrical resistivity at ~277 K appears.
Conclusion
In summary, we show that formation of the secondary metallic Cr2N phase inside CrN during the thin film growth process inhibits the observation of its metal-insulator electronic phase transition. A high Cr-flux during the deposition process results in metallic Cr2N networks inside the CrN matrix. When the Cr-flux is reduced below the critical limit of the growth rate of 1 nm/min, a stoichiometric single-crystalline CrN thin film is obtained that reproducibly exhibits the electronic phase transition. Our results also show that when the Cr2N, inside the high-flux mixed film, is converted to CrN by annealing it inside NH3 environment at high temperature, the electronic phase transition is recovered. This strongly manifests the fact that phase pure and stoichiometric CrN films can show the metal-insulating electronic phase transition. The demonstration of the origin behind the controversy of the metal-insulator transition in CrN thin films marks significant progress for its potential applications in nanoscale devices [3,4,5].
Figure Caption
Figure 1 (a) Low-magnification HAADF-STEM micrograph of the HCF film is presented that shows the presence of both Cr2N and CrN. Inset shows the EDP of the film with cubic [001] and hexagonal

patterns. (b) STEM-EDS elemental maps corresponding to (a) show the spatial distribution and morphology of the Cr2N and CrN grains. (c) HAADF-STEM micrograph of the HCF film with bright regions that represent the Cr2N, while the darker parts showing CrN grains. (d) Cr, (e) N and (f) Cr+N STEM-EDS maps corresponding to the region (c) showing the different grains. (g) HAADF-STEM micrograph of the LCF film showing single-phase epitaxial single-crystalline CrN growth on MgO substrate. (h) Homogeneous and uniform Cr and N atomic distribution in the LCF film is demonstrated by the STEM-EDS map. (i) Atomic-resolution STEM image of the CrN/MgO interface from the LCF film is presented that exhibits cubic epitaxial CrN crystal growth on MgO substrate.

PS-07 (2), Plenary, august 30, 2024, 10:30 - 12:30

Background Incl. Aims
3D images of porous materials in high resolution have been so far obtained using transmission electron tomography or focused ion beam coupled with scanning electron microscopy. These methods require ultra-vacuum conditions, and only a small volume of the sample is visualized. Here, we demonstrate the application of ptychographic x-ray computed tomography for visualizing soft matter with a resolution of 26 nm over large fields of view. We showcase the technique's capabilities by imaging polymer hollow fiber porous membranes.

Porous materials have essential functions in nature, whether for water and nutrient transport in plants and other biological systems or for the storage of oil and water in rock reservoirs. Synthetic polymeric materials are key for chromatography and membrane separation processes. Their application is well-established in water desalination, hemodialysis, gas separation, and is expanding in nanofiltration for chemical separations. The advantages of membrane technology are low energy requirement, and low carbon footprint combined with a compact design that allows packing a large membrane area within a small volume. Effective membranes have a complex porous structure to secure selectivity, mechanical stability, and fast transport characteristics. Porosity and interconnectivity determine the membrane performance.

Thanks to the high-penetration depth of the X-ray beam, we visualize the 3D complex porous structure of polyetherimide ultrafiltration hollow fibers in a non-destructive manner and obtain quantitative information about pore size distribution and pore network interconnectivity across the whole membrane wall. The non-destructive nature of this method, coupled with its ability to image samples without requiring modification or a high vacuum environment, makes it valuable in the fields of porous- and nano-material sciences, enabling imaging under different environmental conditions.

Methods
A highly coherent x-ray beam produced by SIRIUS, the 4th generation synchrotron source inaugurated in 2020 in Campinas, Sao Paulo, Brazil, was used at a dedicated beamline for x-ray imaging - Cateretê. Ptychographic x-ray computed tomography (PXCT) is a lensless coherent x-ray technique, where the specimen is raster scanned in two dimensions by a coherent x-ray beam defined by a pinhole, and diffraction patterns in the far-field are recorded at each position. The

sample is rotated and the 2D scans are collected at different projections to obtain a 3D dataset for reconstructions.

Results
The high-performance computer reconstruction of the collected 2D projections resulted in detailed 3D images of the hollow fibers, with a resolution of 26 nm and a voxel size of 23 nm × 23 nm × 23 nm. Such a detailed model contains not only visual but also quantitative information, and it was used to evaluate the porosity gradient across the membrane walls for hollow fiber membranes. Apart from the porosity, we were able to study the evolution of the diameter size of every detected pore channel across the membrane thickness within the resolution limits (26 nm diameter), to evaluate the pore size distribution and changes across the entire membrane. We could also provide a comprehensive analysis of the interconnectivity of the pores.

Conclusions
The highly coherent X-ray beam generated by the 4th generation synchrotron source allows for the non-destructive analysis via PXCT with nanoscale resolution. The reconstruction of the X-ray coherent diffraction patterns from different projection angles, not only facilitated the visualization of complex porous morphology throughout the entire membrane wall volume but also provided a detailed 3D quantitative model of the porous network. The presented PXCT method is not limited to the measurements of porous structures but can be employed for resolving the nanostructure details in large samples within soft matter. Furthermore, thanks to the high-penetration depth of X-rays, PXCT allows for the analysis of the samples where the sectioning for electron microscopy methods is not feasible. The lack of vacuum requirements and the absence of sample modification, such as heavy metal staining, enable in situ analysis of samples in different environmental conditions. These advantages, coupled with the non-destructive nature of this technique, make it highly applicable in material science and biology for the understanding of complex porous- and nanomaterials offering nanometer-scale resolutions for large sample volumes and providing valuable quantitative information.

How Euro-BioImaging can support your research with access to the best imaging tools

Johanna Bischof[1]
[1]Euro-BioImaging ERIC, Heidelberg, Germany

Poster Group 2

Advanced imaging technologies are a central technology platform driving research in most disciplines of the life sciences and correlating multiple imaging approaches has become an increased need in many research approaches.

Euro-BioImaging's role in the imaging revolution is to offers all scientists open access to imaging instruments, expertise, training opportunities, and data management services beyond what is available at their home institutions or among their collaborators.

The technologies offered by Euro-BioImaging can be accessed at Euro-BioImaging Nodes, which comprise more than 200 internationally renowned imaging facilities distributed across Europe.

They cover the whole spectrum of biological and biomedical imaging. This includes many facilities that offer imaging methods for characterising chemical and physical composition of samples, and the full spectrum of Electron Microscopy solutions - from cryoET to volumeEM and correlative imaging.

In addition to access to cutting-edge instruments, the Euro-BioImaging Nodes provide expertise, guidance and training on all aspects of the imaging experiment - from experimental design and sample preparation to image analysis services, including on external data.

Euro-BioImaging has a strong commitment to Open Science, working with image data repositories such as the BioImage Archive and EMPIAR, as well as offering image analysis and support with data FAIRification.

All scientists, regardless of affiliation, area of expertise, or field of activity, can benefit from Euro-BioImaging's pan-European open access services and funding for user access is available.

For the technical experts at imaging core facilities, Euro-BioImaging provides a cross-European network and platform for exchange of experience, as well as new training opportunities.

Optimizing FIB-based sample preparation for quantitative in-situ biasing studies of semiconductors using 4D-STEM

Vitalii Lider[1], Franziska Hüppe[1], Saleh Firoozabadi[1], Shamail Ahmed[1], Jürgen Belz[1], Andreas Beyer[1], Kerstin Volz[1]
[1]Materials Science Centre and Department of Physics, Philipps University Marburg, Marburg, Germany

Poster Group 2

Background incl. aims

Recent advancements in four-dimensional scanning transmission electron microscopy (4D-STEM) technology have facilitated the precise quantification of electric fields and potential differences at the nanometer scale.[1] To comprehend the operational dynamics of semiconductor devices under applied voltage, operando TEM represents a logical progression. However, measurements require the sample to be properly mounted and brought into contact with the electrical chip. Since the necessary microcontacts are created by focused ion beam (FIB), a systematic study must be carried out on how the sample must be prepared, protected, contacted and thinned consequently. This creates guidelines for quantitative measurements of the amount and path of currents that must flow through the circuit. Once properly quantified, the procedure will help carry out in-situ biasing studies of semiconductor materials and simultaneously measure the built-in potential. Furthermore, this will also help do in situ breakdown study of semiconductors quantitatively.

Methods

In this study, we used a pn junction with doping concentrations and corresponding built-in potential known from electrochemical capacitance-voltage (ECV) measurements. For the characterization within the TEM, the Protochips Fusion holder was used. As a comparison criterion, we chose the IV characteristic curve for different lamella geometries, bulk material and theoretical calculations. Sample preparation leverages the combined advantages of two FIB microscopes: The Helios 5 Hydra CX PFIB and the Jeol JIB-4601F. The former has xenon plasma source which enables faster chuncking. Thanks to the advanced manipulator needle control and appropriate geometry, this microscope provides the solution for lifting out the TEM lamella and attaching it to the biasing chip without complicated intermediate steps. However, it is known that thinning of the lamella with Xe-Beam can cause curtaining.[2] In our case this would be undesirable as it could result in electrical short circuit channels. We can avoid this problem by using the second FIB microscope mentioned above with a gallium-ion source. For the electrical contacts and the protective layer tungsten is used.

Results

The electrical experiments require the smallest possible resistance between the sample and the metal contacts. It is already known from the literature that ion beam induced deposition (IBID) leads to a significantly lower resistance compared to electron beam induced deposition (EBID).[3] Accordingly, the contacts here were made using FIB.
In the following we compare different geometries of the lamellas. Graphic A shows the 'H' shape lamella. This geometry would have the advantage that the same potential can be applied to the

entire p-side. However, the distance between the positive and negative contacts is very short, which leads to a short circuit due to undesirable contamination of the chip surface. This can also be clearly seen in the IV characteristic curve. In graphic B the 'S' shape lamella is shown. This form has the advantage that the positive and negative contacts are at a significantly greater distance from each other. Contamination of the chip surface can also be neglected with this geometry, as the potential drops from the right to the left side across a cut in the chip. This geometry leads to a significant improvement in the behaviour of the IV characteristic, as can be seen in the plot. Graphic C shows the same lamella as B with additional cuts to prevent current flow to the tungsten layer on top. Although the 'S' shape geometry has an improved IV characteristic, it is more similar to a Schottky diode than a pn diode. However, this is not surprising, because the contacts are on the same size scale as the lamella. This must be considered in the theoretical calculations in order to be able to quantify what proportion of the externally applied voltage drops at the pn junction.

Conclusion

This study highlights the importance of careful sample preparation techniques for in-situ biasing studies of semiconductor materials using 4D-STEM. By optimizing the FIB-based preparation and lamella geometries, we have achieved improved IV characteristic behaviour and a lower amount of short circuits. However, the metal-semiconductor contacts must be carefully considered in the descriptive models. These results will provide practical insights for improving measurement accuracy and reproducibility in operando TEM studies of semiconductor devices and may contribute to advances in electronic device development.

Inversion of the Internal Electric Field in GaN/AlN Heterostructures Studied by Off-Axis Electron Holography

Lou Denaix[1], Dr Florian Castioni[1], Dr Matthew Bryan[1], Dr David Cooper[1], Dr Eva Monroy[2]
[1]Univ. Grenoble Alpes, CEA, Leti, Grenoble, France, [2]Univ. Grenoble Alpes, CEA, Grenoble INP, Irig, Pheliqs, Grenoble, France

PS-03 (2), Lecture Theater 2, august 30, 2024, 10:30 - 12:30

Background incl. aims
Wurtzite III-nitride semiconductor are renowned for their applications in light emitting devices, due to their wide bandgap and doping capabilities. One of the main challenges of these materials is managing their intense spontaneous and piezoelectric polarization fields. In order to enhance the efficiency of GaN-based emitters, it is important to design new architectures to engineer the electric field in these materials. In addition, validation of these new designs requires the development of characterization methods capable of mapping the electric fields with nanometer resolution.
In this work, we study the effect of n-type delta doping on the potential profile of AlN/GaN and AlGaN/GaN superlattice using off-axis electron holography for the quantification of the electrostatic potentials. In addition, the sample composition, and the concentration and localization of dopants are determined using correlative techniques: high-resolution electron dispersive X-Ray spectroscopy (EDX), secondary ion mass spectroscopy (SIMS) and Nextnano simulations.

Methods
The samples under study consist of 10-periods of AlN/GaN (20 nm/20 nm) (1st series: samples S1 and S2) or 12 periods of AlN0.3Ga0.7N/GaN (15nm/15nm) (2nd series: samples S3, S4 and S5) grown by plasma-assisted molecular beam epitaxy. In the first series, S1 is non-intentionally doped and S2 is heavily doped with Ge in the GaN layers, at a nominal concentration [Ge] = 2.0±0.2 × 1021 cm−3, which is close to the solubility limit. In the second series, S3 is non-intentionally doped and S4 and S5 have a delta doping of Ge ([Ge] = 1020 cm-3) and Si ([Si] = 1019 cm-3), respectively, localized in the AlGaN layers. The dopant concentrations are measured by SIMS.
The electrostatic potential of the samples are measured by off-axis electron holography performed in a double-corrected FEI Titan Ultimate TEM operating at 200 kV. The electron holograms were recorded on a Gatan OneView 4k camera. EDX-spectroscopy was performed in a probe-corrected FEI Titan Themis microscope operated at 200 kV and equipped with a Super X detector system. EDX spectra quantification was done using the Cliff-Lorimer method.

Results
Using electron holography in undoped AlN/GaN and AlGaN/GaN samples (S1, S3), we confirm the presence of internal electric fields in the GaN and AlN layers, with a sign that is consistent with Schrödinger-Poisson simulations performed with the Nextnano software. Then, comparing S1 and S2, we are able to demonstrate the effect of carrier screening due to Ge doping. However, we also observed an inversion of the internal electric field in some of the AlN layers in S2. A correlative study involving holography, EDX and theoretical calculations of the band diagram demonstrate that this inversion can be attributed to Ge accumulation at the heterointerfaces in the AlN layers [1]. These result pave the way to the use of delta doping as a design tool to modulate and even invert the electric field in polar heterostructures.

The second sample series (S3, S4 and S5) presents our attempt to reproduce intentionally the inversion of potential observed in S2 by designing AlGaN/GaN heterostructures using delta doping with silicon and germanium. In this case, we observe a systematic inversion of the internal electric field using Si doping. However, this inversion was not observed for Ge delta-doping. Further analysis using SIMS showed a migration of Ge in the GaN layer that explain this absence of inversion. This migration is consistent with our observations of a higher solubility limit of Ge in AlGaN compared with GaN [2], and is coherent with the Ge clustering observed in S2.

Conclusion

We show here that electron holography is a very powerful tool that allow the measurement of electrostatic potential with a nanometer resolution. It is particularly useful to study III-nitride materials that present peculiar electrostatic properties. We apply it here to study first the efficiency of germanium doping to screen the polarization-induced internal electric field in AlN/GaN superlattices. In addition, our identification of electric field inversion domains associated with Ge inhomogeneities paves the way for the use of delta doping as a tool in the design of heterostructures, to modulate and even invert the electric field in polar heterostructures. We have also addressed the effect of delta-doping in AlGaN/GaN, showing that inversion of the electric field is also possible using Si delta-doping, with improved reproducibility. Our studies show that the incorporation of germanium in III-nitride heterostructures remains challenging, with issues such as dopant segregation and dopant migration, but silicon delta-doping is also a very promising tool for fine-tuning of the internal electric fields in these materials.

This work, carried out on the Platform for Nanocharacterisation (PFNC), was supported by the “Recherche Technologique de Base” and "France 2030 - ANR-22-PEEL-0014" programs of the French National Research Agency (ANR).

Multi-modal correlative microscopy: simultaneous and colocalised Raman & SEM imaging

Dr Jorge Diniz[1], Miss Jennifer Ferguson[1], Mr Pete Johnson[1], Mr Tim Smith[1]
[1]Renishaw plc, New Mills, Wotton-under-Edge, UK

Poster Group 1

Multi-modal sample analysis is essential to thoroughly characterise and understand our samples and materials and ultimately conduct cutting edge science.
Here we focus on 4 different modalities: Raman spectroscopy, optical imaging, SEM (scanning electron microscopy) imaging and EDS (energy dispersive X-ray spectroscopy). These techniques allow us to determine chemical composition, molecular and crystalline structure (Raman spectroscopy), collect optical images, image samples at high resolution (SEM imaging) and determine elemental composition (EDS). When combined, these techniques provide an excellent toolbox for sample characterisation.
Measurements were conducted using an inLux™ SEM Raman interface attached directly to the SEM microscope. This enabled colocalised and simultaneous SEM, Raman, and optical imaging inside the SEM chamber, making correlation between the three techniques trivial, without ever moving the sample.
Figure 1 illustrates SEM, EDS and Raman images taken from a mineral section, demonstrating a clear and accurate overlay between minerals found with three techniques. Additionally, the complementary potential of the multi-modal analysis showed species detected only with Raman (anatase) or EDS (Zn, sphalerite). The presence of anatase also shows that Raman spectroscopy is sensitive to the many polymorphs of TiO_2.
The application potential of correlative SEM and Raman imaging will also be demonstrated on batteries, polymeric and biological samples. With these examples, we illustrate how Raman and SEM can increase understanding of materials, and the power and ease of use when the techniques are combined inside a SEM.

Near-Ideal Direct-Electron Focused-Probe 4D-STEM Data for Open-Source Phase Reconstructions

Prof. Toma Susi[1], Niklas Dellby[2], Russ Hayner[2], Christoph Hofer[3], Jani Kotakoski[1], Tracy Clark Lovejoy[2], Clemens Mangler[1], Andreas Mittelberger[2], Timothy J. Pennycook[3], Benjamin Plotkin-Swing[2]
[1]University of Vienna, Faculty of Physics, Vienna, Austria, [2]Nion Co. R&D, Kirkland, USA, [3]EMAT, University of Antwerp, Antwerp, Belgium

IM-03 (4), Plenary, august 29, 2024, 14:00 - 15:00

Background incl. aims
The availability of direct-electron cameras with high dynamic ranges and very fast detection speeds is revolutionizing the ability of scanning transmission electron microscopy (STEM) to make use of every electron for virtual imaging and advanced computational phase reconstructions. State of the art detectors can now acquire four-dimensional (4D) data at STEM pixel dwell times of over 100,000 diffraction patterns per second while counting each electron.

At the same time, the proliferation of open software packages to make use of this data has made such analyses widely accessible, and due to a convergence to the Python programming language, easy to compare in terms of computational efficiency and reconstruction quality.

Methods
The first commercially available Dectris ARINA detector [1] has been installed in the Nion UltraSTEM100 instrument in Vienna, where an ultra-stable sample stage and flexible electron optics are ideally suited to 4D-STEM. For our initial comparisons, we use an atomically focused probe (34 mrad convergence semi-angle) and choose a camera length optimized for maximum signal in the bright-field and the first-order Bragg disks.

In this contribution, we present some of the first data acquired on this new detector, namely convergent-beam electron diffraction maps of pristine monolayer graphene, which is a near-ideal dose-robust uniform atomic phase object. The ability to reliably count electrons at such speeds (the detective quantum efficiency is 0.85 at 60 keV [1]) also enables the variation in beam current to be easily measured and, if desired, corrected for, which we find has an appreciable impact on the bright-field signal and reconstructions that make use of it (most notably parallax imaging [2]).

Results
A pixel exposure time of 100 µs provided a high signal for phase reconstructions without needing to resort to multi-frame averaging. The ARINA is able to bin the native 192×192 detector array in hardware for faster acquisition, and we find that further software binning up to four times does not harm reconstructions, whereas a dense real-space sampling below 0.08 Å per pixel (512×512 px scan over the 2×2 nm² field of view) was noticeably helpful.

The graphic shows the concurrently acquired high-angle annular dark-field (HAADF, 80–300 mrad) and virtual ADF images (~40–80 mrad), as well as a range of open-source phase reconstructions from the binned 4D dataset: single-sideband (SSB) and Wigner distribution deconvolution (WDD) [3], as well as iterative differential phase contrast (DPC), parallax-corrected bright-field imaging, and batched iterative gradient descent single-slice ptychography [2]. Apart from modest scan distortions,

visual inspection of the phase images reveals deviations from the expected uniform atom contrast, and notable differences in phase magnitudes. Computational times also vary greatly depending on the algorithm and the binning.

Conclusion
The quality of the phase images is assessed by evaluating the variation of atomic phase shifts using a robust parameter-based quantification method [4] and compared to data simulated with the abTEM code [5] and reconstructed with the same algorithms. These quantitative comparisons will be presented at the meeting, where the data and code will also be provided. Further results on defocused-probe datasets and the prospects for live reconstructions will be discussed.

A Secondary Electron Hyperspectral Imaging characterisation of mechanochemically functionalised carbon black materials

James Nohl[1,2], Nicholas Farr[1], Maria Rosaria Acocella[3], Serena Cussen[4], Cornelia Rodenburg[1]
[1]Department of Materials Science and Engineering, The University of Sheffield, Mappin Street, Sheffield, UK, [2]The Faraday Institution, Quad One, Becquerel Avenue, Harwell Campus, Didcot, UK, [3]Department of Chemistry and Biology " A. Zambelli", University of Salerno, Via Giovanni Paolo II, 132- 84084 Fisciano, Italy, [4]School of Chemistry, University College Dublin, Belfield, Dublin 4, Ireland

Poster Group 2

Background
Carbon blacks find applications in composite materials for energy generation and storage, structural materials, as well as catalysis and as precursor materials. In nanocomposite applications of carbon black, the surface functionalisation of the carbon black is important in determining the structure of the composite and the function of the material [1]. Powders in this form are often characterised as a bulk material, however it is important to understand the local surface chemistry and distribution of chemistries between particles, particularly when the surface of the powder is engineered to achieve certain properties.
Such is the case with carbon black subject to surface oxidation processes. In this case, a one-step ball milling process was used to vary the particle morphology and surface oxidation [2]. X-ray photoelectron spectroscopy (XPS) can tell average oxidation. Transmission electron microscopy (TEM) can tell particle size and surface chemistry – but not for in-situ satellite particles. Therefore, a study which includes local information about particle morphology and functionalisation with process time, may offer insight into the dynamics of the process which includes fracturing, agglomeration, exfoliation and oxidation.
Secondary electron hyperspectral imaging (SEHI) proved to be a valuable technique for characterisation of polymers functionalised by plasma surface treatment [3]. Here we show the technique is applicable to a nano materials characterisation challenge to image the morphology and local surface chemistry of satellite particles in-situ produced during milling on bulk carbon black particles.

Methods
The carbon blacks characterised by SEHI were as-received carbon black and carbon black ball milled without solvent at room temperature for a total of 0h, 1h, 5h, 9h and 11h. Average spectra from 20 µm horizontal field width images were produced for the as-received carbon black and each ball milling process time. A functionalised carbon black model was fitted to spectra to obtain component peak heights using the lmfit python module (Figure 1a). Ratios of peak heights for CH (hydrogenated amorphous carbon) and OH functionalised carbon to sp^2-hybridised graphitic carbon were calculated (Figure 1b). The energy ranges 2.2-2.8 eV, 3.0-3.6 eV, 4.2-4.9 eV and 5.4-6.0 eV were used to create colour maps related to sp^2, CH, OH and CO+sp^3 surface functionalities respectively (Figure 1c). These component images were assigned to channels with hue values equidistantly spaced in the HSV colour space (Figure 1d). The composite map is a sum of these component images (Figure 1e).

Results
The CH:sp^2 ratio decreases from 1.05 to a minimum of 0.5 at 5h milling time, then increases to 1.4 at 11h. The OH:sp^2 ratio decreases from 1.3 to a minimum of 0.8 at 5h milling time then increases to a

maximum ratio obtained by processing of 1.3 at 9h. Further milling to 11h decreases the OH:sp^2 ratio to 1.1 (Figure 1b). The results indicate that the sp^2 surface content is maximum at 5h. Further milling up to 9h oxidises the surface but more milling post 9h produces more amorphous hydrogenated carbon surfaces.
At 5h, the composite colour map indicates a nanoscale 'satellite' particle morphology (see Figure 1d inset for a line profile indicating the particle size) with strongest emissions in the OH component range.

Conclusions
SEHI added to the understanding of the carbon black material by analysing the local chemistry of 'satellite' nano particles which were more oxidised versus the bulk carbon black particle. This is not clear from spatially averaged XPS analyses of the powder.
Meanwhile, a spatially averaged SEHI analysis identified components for carbons and surface carbon compounds. A qualitative comparison of the CH and OH to sp^2 ratios versus ball milling time in oxidative conditions showed a maximum of sp^2 surface chemistry by 5h before this was oxidised to the highest OH:sp^2 ratio at 9h and the highest CH:sp^2 at 11h.
Local characterisation enhances understanding of how the processing influences surface chemistry and morphology resulting from process time.

Temperature-driven in-situ TEM cation exchange at the solid state: a combined experimental and computational study

Alberto Casu[1], Mr. Claudio Melis[2], Mr. Luciano Colombo[2], Mr. Andrea Falqui[1,3]
[1]Department of Physics, University of Milan, Milan, Italia, [2]Department of Physics, University of Cagliari, Monserrato, Italy, [3]Interdisciplinary Centre for Nanostructured Materials and Interfaces (CIMaINa)- Department of Physics, University of Milan, Milan, Italy

PS-01 (2), Lecture Theater 3, august 28, 2024, 14:00 - 16:00

Background including aims
Over the past two decades, the demand for innovative nanomaterials has surged due to their remarkable adaptability across various fields such as optoelectronics, photonics, and catalysis. This has led to the development of robust synthetic techniques to produce nanocrystals (NCs) with finely tuned compositions, crystal phases, and morphologies.
Post-synthetic transformations of preformed nanostructures can be singled out among the available methods as a general approach to produce nanomaterials with features unattainable through conventional synthetic routes. Cation exchange (CE) is a prominent example this approach, because it is based on the substitution of cations within a host NC lattice, offering precise control over compositions and phases without affecting the NCs' morphology. Understanding the underlying mechanism of CE reactions is crucial for the rational design of nanostructures, but previous approaches to elucidate it relied on analyzing intermediate samples extracted during CE reactions in liquid state, and were hindered by the rapid kinetics of liquid-phase reactions and limited sampling capabilities. To overcome these limitations, solid-state observations of CE reactions were conducted using an in-situ transmission electron microscopy (TEM) approach. This technique enables continuous monitoring of CE reactions with enhanced detail over extended time frames, thanks to the slower kinetics of solid-state reactions and the rapid sampling afforded by TEM. After proving the feasibility of solid-state CE reactions, the focus was moved towards understanding CE reactions and their early stages through a combined experimental/computational approach. The experimental studies focused on in-situ TEM experiments utilizing advanced microelectronic mechanical systems (MEMS)-based heating holders for precise heating control, high-resolution scanning TEM (HRSTEM) imaging coupled with electron energy loss (EELS) and energy dispersive X-ray spectroscopy (EDS) for detailed chemical analysis, and the introduction of different crystal structures to examine variations in CE reactions. The results of these studies constituted the starting point for a comprehensive theoretical study employing classical molecular dynamics (MD) simulations, conducted to provide numerical estimations of activation energies and elucidate the factors influencing CE reaction dynamics. This combined experimental and theoretical approach offers a comprehensive framework for understanding and manipulating CE reactions, shedding light on their intricacies and potential applications in nanomaterial design.
Methods
In-situ TEM and its ancillary techniques were used for the experimental studies on CE reactions at the solid state involving Cu2Se NCs (cation donors) and CdSe nanowires (NWs) with cubic and hexagonal crystal structure (cation acceptors). The mixed populations were closely monitored against temperature using a MEMS-based in situ heating holder. HRSTEM and STEM-based chemical mapping were used to observe the initial phases of CE and analyze the local chemical compositions. MD was used for the calculations related to the atomistic CE model, which included portions of CdSe NWs

initially surrounded by Cu atoms, and a suitable force-field (FF) was adopted to replicate mutual interactions occurring between Cu atoms and CdSe matrices across both crystal structures.
Results
Two parallel studies investigating CE reactions between Cu2Se nanospheres and hexagonal CdSe NWs or cubic CdSe NWs were conducted by a combination of HRSTEM, STEM-EDS mapping and STEM-EELS-based spectrum imaging, with particular attention devoted to early-stage CE. For this reason, available copper was deliberately minimized during the experimental design to slow CE reaction rates. Both studies revealed the formation of distinct CE fronts, negligible direct influence from Cu2Se nanospheres and the presence of a thin Cu layer around the NWs prior to the actual CE. However, the activation temperatures and CE rates changed drastically from one system to the other, going from 400 °C for hexagonal CdSe NWs to 125 °C for cubic CdSe NWs. Also, an unstable regime was observed for cubic CdSe NWs up to 250°C, allowing for partial reversibility of exchanged Cu2Se domains into CdSe.
An atomistic model developed via classical MD simulations provided a theoretical framework for the experimental results, aiming to pinpoint specific local mechanisms involved in CE and to quantify their respective contributions to the overall process. The CE reaction was divided into 4 sequential steps: formation of a Cu shell around a CdSe NW; penetration of Cu atoms into the CdSe NW and subsequent creation of Cu interstitial defects; diffusion of Cu interstitial defects within the CdSe matrix; Cu to Cd substitution via a kick-off event. Each step was simulated to estimate the corresponding activation energy and interatomic interactions in CdSe and Cu2Se were modeled using a combination of Lennard-Jones and Coulombic terms, adapted from the CdSe FF to describe CdSe and Cu2Se structures. MD simulations were conducted for both cubic and hexagonal CdSe structures, revealing differences in energy barriers and migration energies. Notably, cubic CdSe exhibited lower energy barriers, suggesting a more favorable CE process. The model predictions align well with experimental observations for both systems.
Conclusions
In-situ TEM studies on thermally-activated CE reactions at the solid-state between Cu2Se NCs and hexagonal or cubic CdSe NWs were carried out employing a MEMS-based heating holder to explore the early stages of CE and how the acceptor's crystal structure influences the CE process. Notably, expelled copper forms an external shell around CdSe NWs before CE starts and it was found that CE reactions exhibit different threshold temperatures (400°C for hexagonal CdSe and at 125°C for cubic CdSe) and kinetics depending on the host matrix's crystalline phase, with an unstable regime observed for cubic CdSe NWs at low temperatures.Classical molecular dynamics simulations were employed to numerically estimate activation energies and elucidate the probabilities of the entire CE process for different CdSe crystal structures, leading to a good agreement between experimental and computational results. This combined experimental and theoretical approach not only enhances our understanding of thermally activated CE but also sheds light on the mechanisms governing CE reactions with unprecedented detail, particularly in relation to the influence of nanoparticle crystal structure on reaction dynamics.

Advanced electron microscopy study of Cu coated Boron Nitride sheets

NITUL Rajput[1], Mr Abdullah Al Shehhi[1], Dr Monserrat Gutierrez[1], Dr Afra Al Ketbi[1]
[1]Technology Innovation Institute, Masdar, United Arab Emirates

Poster Group 1

Nitul Rajput1, Abdullah Al Shehhi 1, Monserrat Gutierrez 1, Afra Al Ketbi1
1Advanced Materials Research Center, Technology Innovation Institute, PO Box 9639, Masdar City, Abu Dhabi, United Arab Emirates

Background incl. aims
Since the advancement of additive manufacturing in recent years, integrating 2D materials with metal alloys has been seen as a promising route in the enhancement of thermal and mechanical performance of the printed material. However, intermixing 2D materials with metal alloys poses various challenges and nanomaterial agglomeration has remained one of them. Coating the 2D materials with metal elements could be a way to overcome such issues. In this work, we have implemented an electroless plating method to coat Boron Nitride (BN) sheets (a ceramic material) with Cu for the development of next generation metal alloys for additive manufacturing. However, evaluating the coating efficiency has seemed to be a challenging task. Hereby, we have developed a protocol of using advanced electron microscopy-based techniques to efficiently characterize the coated material and evaluate the coating efficiency.

Methods
For the study, the vacuum filtered coated powder material was glued on a Si substrate. We have employed various electron microscopy-based methods and developed a protocol to examine the coating efficiency. In-lens backscattering imaging in combination with energy dispersive spectroscopy in a Scanning electron microscope has become a primary observation tactic. Subsequently, thin lamellas were prepared from the Cu-coated BN sheets for evaluation in TEM. Additionally, High angle annular dark field – Scanning transmission electron microscopy (HAADF-STEM) was implemented at a reasonable camera length to observe the intermixed system. Further, electron energy loss spectroscopy (EELS) was performed on the Cu-coated BN sheets.

Results
Initial investigation with the in-lens backscattering detector in SEM along with EDS mapping provides a fundamental understanding of the coated material. Backscattering SEM imaging is sensitive to the material (atomic number) and Cu appears brighter as compared to the BN sheets. Followed by the initial study, Focused ion beam (FIB) was used to make cross-sectional sample and viewed (backscattering SEM) to gain information about the internal structure of the coated material. Subsequently, TEM lamellas are prepared, and high-resolution TEM images are taken which shows high degree of crystallinity of BN and Cu metal interface and provides intricate information about the plating process. Further, STEM-EELS mapping was carried out on the BN-Cu matrix that shows successful coating of the BN sheets.

Conclusion
We have presented a methodology to characterize nanomaterials coating (Cu coated BN sheets) using advanced electron microscopy techniques. The results indicate successful coating of Cu on BN

sheets and hereby confirm the efficacy of the coating procedure. The developed systematic protocol to implement advanced electron microscopy techniques to evaluate the Cu-coating of BN sheets can be used/extend to study other metal-2D material coating or multi-elemental matrix system.

Second harmonic generation microscopy of femtosecond microstructured crystals

Nuria Sevilla Sierra[1,2], Dr. Javier Rodríguez Vázquez de Aldana[1,2], Dr. Carolina Romero[1,2], Dr. Xavier Mateos[3], Dr. Ignacio Lopez-Quintas[1,2]

Poster Group 2

Background incl. aims
Second Harmonic Generation (SHG) is a non-linear parametric optical process that implies the creation of one 2ω frequency photon while destroying two photons of frequency ω. It can only happen in non-centrosymmetric materials with non-vanishing second order susceptibility χ(2), such as anisotropic crystals or fibrillary microstructured biological tissues. There is a quadratic dependence of the SHG field with the fundamental ω one, which implies that the efficiency of the process increases with laser power, and thus, to generate measurable 2ω signals, ultrashort laser pulses are the most suitable sources. Second Harmonic Generation Microscopy (SHM) is a technique based on scanning the sample with a strongly focused ultrashort laser while measuring the SHG signal that is generated at each scanned position of the sample: since the main nonlinear laser-matter interaction is strongly restricted to the focal volume, the measurements are intrinsically confocal and therefore allow for precise 3D sectioning. The SHM technique can reveal rich morphological and structural information in the micro-scale, non-linear properties and/or different chemical composition of the sample.
Methods
Ultrashort femtosecond laser pulses can nano- and micro-structure transparent solids, locally modifying with high spatial precision their index of refraction. In this work we have investigated the non-linear response of two different previously micro-structured crystals: a non-centrosymmetric crystal (β-BaB2O4, BBO) and a centrosymmetric one (Nd:YAG). A femtosecond laser system (writing laser) was used to irradiate the sample in order to produce micro-modifications inside the crystal bulk. Different sets of irradiations were carried out both in BBO and Nd:YAG samples. A homemade microscopy set-up, able to operate as a conventional optical microscope and as a non-linear microscope, was used for the SHM measurements. In the non-linear mode of operation, the sample was illuminated with 120 fs laser pulses (measuring laser) with a central wavelength of 795 nm delivered by a Ti:Sapphire oscillator at a repetition rate of 80 MHz. For this study, SH maps were obtained by scanning the sample by moving the focusing point along the laser-inscribed tracks, which results in spatial variations of the signal intensity that can be measured and precisely assigned to their XYZ point of generation.
Results
BBO is one of the most widely used non-linear crystals due to its high optical non-linearity, wide range of transparency and physical robustness. It has the possibility to phase-match the SHG process in a large spectral window ensuring efficient conversion. In this work it was demonstrated that, under certain conditions, the SHG process in the damage tracks created by ultrashort laser irradiation exhibits a local enhancement in extraordinary polarization conditions. This phenomenon is attributed to a modification, achieved with the micro-structuring, of the effective non-linear coefficients of the

susceptibility tensor, where irradiation modifies coefficients that take part in the extraordinary polarization conditions but not in the ordinary polarization situation. It can also be attributed to a modification of the Gouy phase, because the irradiation and consequent breakage of symmetry in the crystals prevents phase compensation, thus allowing SHG signal to appear.
The second crystal studied, Nd:YAG, has a centrosymmetric structure. The generation of SH signal, localized at the damage tracks, was confirmed, and its features analyzed in detail in terms of the irradiation parameters of the inscribed micro-modifications. Findings show that the SH signal increases when increasing the inscription pulse energy, and when the scanning velocity is reduced (increased pulse overlap). It can be also seen that the measurement laser polarization has a significant effect on the intensity of the SHG signal.
The micro-modifications induced in the YAG structure by the laser irradiation explain the origin of this effects. These include a locally modified crystalline state (different inter-atomic distances; presence of lattice defects) and the formation of periodic structures or nanogratings in the amorphized region, along with phase transformation that can be found at the tracks. Due to the change in the inter-atomic distances in the dislocation surfaces or to a breakage of the inversion symmetry at the boundary between the crystal and the amorphous region, both, dislocations and the presence of an amorphized region, can be responsible for the generation of SH. In this case, the laser polarization for a more efficient SH signal is the one perpendicular to the interface, since it is the field orientation that probes the damage-induced anisotropy.
Conclusions
The observed nonlinear phenomena allow the use of SHM as a powerful technique for 3D imaging and diagnosing of photonic devices micro-structured by femtosecond lasers, such as optical waveguides or micrograting. Although the technique has been extensively employed in non-linear materials, these results open the possibility of waveguide or integrated photonic devices fabrication in centrosymmetric materials that are not initially expected to have a non-linear response.

Latest developments in accurate and high-throughput correlative cryo-FIB milling for cryo-ET lamella production

Marit Smeets[1], Deniz Daviran[1], Wessel Teunisse[1]
[1]Delmic B.V., Delft, The Netherlands

Poster Group 1

Correlative cryo-FIB milling is a powerful sample preparation technique for in situ cryo electron tomography (cryo-ET). Using this technique, vitrified cells can be thinned down and cellular components can be directly visualized in their native context at near-atomic resolution. In recent years several solutions have been proposed to simplify the technique by integrating fluorescent microscopes (FLM) in the cryo-FIB. However, it remains challenging to quickly and accurately target the region of interest (ROI). Here we present a high-quality integrated fluorescent microscope, called METEOR, that allows quick and accurate targeting of the ROI.

To ensure accurate targeting the components of METEOR were carefully selected. We ensured it is compatible with objectives with high numerical apertures (NA), the highest being 0.9. The high-end camera brings background noise to an absolute minimum and provides an exceptional quantum efficiency allowing researchers to image challenging and dim samples. The system is equipped with a filter wheel which can be filled with single-bandpass filters avoiding fluorescent bleed-through. Additionally we developed software that allows FLM imaging, sample stage control and SEM and FLM correlation.

By measuring over a 100 sub-diffraction beads we found that the resolution of the METEOR provided 385 nm lateral resolution and 1.18 um axial resolution when using a 50x/0.8 NA objective. This is in line with the theoretical resolution of such an objective. We also found that by integrating FLM and SEM correlation within the FLM acquisition software the SEM map could be used for navigation. This significantly speeds up the identification of suitable cells for milling..

The METEOR system is a high quality imaging platform that allows accurate identification of regions of interest within the challenging samples. The software provides additional benefits that speed up the workflow significantly. METEOR therefore provides an accurate and high-throughput correlative cryo-FIB milling workflow.

Poster Group 1

Combining different complementary analytical methods into one instrument is a powerful technique for the contemporaneous acquisition of both structural and functional sample properties. Especially the combination of atomic force microscopy (AFM), scanning electron microscopy (SEM), and electrical nanoprobing can yield completely new insights for the study of various samples and nanostructures.
In this work, we introduce a highly integrated correlative microscopy platform, that seamlessly combines AFM and SEM within a unified coordinate system. In addition, a three-axis sample stage and a trunnion provide unique experimental capabilities such as profile view – an 80-degree tilt of the combined sample stage and AFM giving full SEM access to the cantilever tip region. This microscopy platform can easily be combined with a nanoprobing system that enables precise electrical characterization of nanoscale structures, offering insights into device functionality and performance. [1-2]
We present a variety of novel case studies to highlight the advantages of this new tool for interactive, correlative, in-situ nanoscale characterization of different materials and nanostructures. Initial results will focus on the analysis of mechanical and electrical properties of individual nanowires. The combination of SEM and nanoprobes enables easy manipulation and positioning of individual nanowires, whereas the in-situ AFM allows the characterization of topography, surface roughness, mechanical and electrical properties of the nanowire.[3-4] Using the SEM's high-resolution the AFM cantilever tip can be precisely positioned on an individual nanowire that is attached to the nanoprober and the topographical and mechanical properties can be determined (see Figure).
In addition, we will show results for electrical nanoprobing of semiconductor devices in combination with conductive AFM measurements. A semiconductor device can be electrically probed by simultaneous use of two nanoprobers while the AFM provides detailed information on the 2D conductance map of the device itself.
Based on the broad variety of applications regarding the inspection and process control of different materials and devices, we anticipate that this new inspection tool will be one of the driving characterization tools for correlative analysis on the nanoscale.

TEM Investigations on the Impact of Hydrogen on Phase Transformations in Aluminum Alloys

M. Omar Boukir[1], M. Xavier Sauvage[1], M. Kaveh Edalati[2]
[1]Univ Rouen Normandie, INSA Rouen Normandie, CNRS, Groupe de Physique des Matériaux UMR 6634, F-76000, Rouen, France, [2]2WPI, International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, Fukuoka 819-0395,, Fukuoka, Japan

PS-02 (1), Lecture Theater 5, august 28, 2024, 10:30 - 12:30

Background :
This study investigates the influence of hydrogen on phase transformations in aluminium alloys, materials of critical importance to the transportation industry due to their superior strength-to-weight ratio[1]. Given the potential of hydrogen to induce hydrogen embrittlement (HE) in metals and alloys, this investigation is of paramount importance. The mechanisms behind HE involve the interactions between hydrogen and crystalline defects such as dislocations, vacancies, grain boundaries, and interfaces[2]. However, understanding these mechanisms has been challenging due to difficulties in localizing hydrogen. Phase transformation, including precipitation, is governed by nucleation sites, atomic mobility, and interface energies, all associated with crystalline defects. Utilizing advanced microscopy techniques, this work aims to indirectly gather information on how hydrogen interacts with defects by examining the influence of hydrogen on phase transformation.
Methods :
The materials under investigation were two aluminum alloys: Al-Cu, chosen for its excellent contrast in STEM-HAADF and its well-known precipitation sequence, and Al-Zr, selected for the strong interaction between zirconium and hydrogen[4]. The JEOL ARM-200F microscope, equipped with a STEM corrector, serves as the primary tool for characterizing structural changes under various conditions, complemented by Atom Probe Tomography (APT) and Thermal Desorption Spectroscopy (TDS) for elemental analysis and hydrogen trapping state investigation, respectively. Precipitates were analyzed under different zone axes to assess their shape and diameter, Additionally, Energy Filtering Transmission Electron Microscopy (EFTEM) was employed to produce thickness maps, enabling the calculation of precipitate density. The distribution of dislocations varied with each state, characterized using both bright field and dark field modes in TEM, and more precisely with the LADF detector in STEM, where dislocations predominantly aligned along (111) planes.
Results and Conclusions :
Findings for the Al-Cu alloy indicated a significant slowdown in the initial aging hardening kinetics in hydrogen-charged samples. STEM-HAADF imaging revealed a reduced precipitate density compared to uncharged samples, suggesting that while hydrogen does not alter the precipitation sequence, it does influence the growth and coalescence rates of precipitates. This effect was even more evident under high hydrogen pressure, especially in extensively deformed samples, indicating a slowdown in precipitation processes and defect recovery. In contrast, the Al-Zr alloy's hardness measurements showed no noticeable difference between samples aged in hydrogen and air. However, TEM analysis revealed that under hydrogen, the diameter of zirconium precipitates was twice as large as those aged in air, with a similar nucleation rate for both conditions. This suggests that hydrogen enhances zirconium diffusion, accelerating precipitate growth.

Poster Group 1

Background incl. aims
Diabetic (DB) wound treatment is still an important problem due to chronic non-healing ulcers that can become infected and lead to amputation. Platelet Rich Plasma (PRP) is a Cellular Therapy (CT) product that has been frequently used nowadays. Probiotics (PB) accelerate healing through the changes they make in the intestine. This study aimed to examine the contribution of PB to the effects of PRP in diabetic wound healing.
Methods
The diabetic model was created by intraperitoneal application of 45 mg/kg Streptozotocin. A 1x1 cm2 full-thickness skin wound was created in those with fasting blood sugar (FBS) above 250 mg/dI. Mature Albino rats were divided into four group (n:5, each) as DB, DB+PRP, DB+PB and DB+PRP+PB. PRP solution prepared as 100uL was used for 10 subcutaneous 10uL applications to the wound edges. PB was administered orally at a dose of approximately 200 mg/day, once a day, starting with the experiment and until euthanasia. During the seven-day experiment, the PB group was fed by gavage every day. Formalin fixed parafine embedded sections were analysis with Hematoxylin & Eosin and Masson's Trichrom histochemical staining methods. Immunohistochemical analysis was performed with eNOS, Caspase 3, IL10, VEGF and Collagen I primary antibodies.
Results
It was observed that the diabetic wound closed significantly faster with PRP. It was determined that healing speed increased significantly and there was a better recovery with PB. It was shown that increased eNOS and Caspase 3 immunoreactivities and decreased IL10, VEGF and Collagen I immunoreactivities during injury were reversed by PRP+PB. It was found that PB application made a significant contribution to the positive effects and reversed parameters realized with PRP.
Conclusion
Preventing oxidative stress and apoptosis, increasing anti-inflammation, vascularization, numerical cell support of connective tissue and signaling pathways with PRP supplemented with PB made a significant contribution to wound healing. It turns out that PB support may be important for difficult-to-heal DB wounds. It was thought that this contribution could further improve the impaired life quality of patient's.

Asbestos Analytics In Relation To Changes Of The European Directive

Bianca Gasse[1]
[1]Institute for Occupational Safety and Health of the German Social Accident Insurance, Sankt Augustin, Germany

Poster Group 1

In 2023, the EU Parliament passed a resolution to amend the Asbestos Directive. Within a transitional period of 6 years, laboratories must either implement a detection limit of 2000 F/cm³ for the evaluation of workplace measurements and or determine fibres thinner than 200 nm (lower limit has not been defined) using electron microscopic methods (phase contrast microscopy is no longer applicable) in order to be able to apply a limit value of 10,000 F/m³.
This poses challenges for analysis. On the one hand, not every laboratory has suitable equipment to fulfil the requirements, on the other hand, the users of the equipment are usually not scientists who are fully familiar with the equipment, but users who follow laboratory instructions. The lecture or poster presents the pitfalls of SEM/EDS analysis in relation to air samples that are to be expected when detecting thin asbestos fibres.
If the detection limit is lowered, at least a semi-automatic evaluation is necessary, as otherwise the analysis times will be unacceptable.
When evaluating asbestos fibres with a diameter of less than 200 nm, two fundamental distinctions must be made. These are the visibility of fibres in the SEM and identification using EDS. The former is certainly dependent on the choice of device (device with Wolfram cathode or field emitter), but also on the choice of detector (SE or BSE detector), primary energy, working distance, brightness, contrast and other parameters. Settings at which fibres with a diameter of 200 nm or larger can be displayed may not be optically recognisable for fibres that are significantly thinner. If an acceleration voltage that is too low is selected, this can make it impossible to identify the fibres, depending on the EDS system used.

Quantum Wavefront Shaping with a 48-element Programmable Phase Plate for Electrons

Francisco Vega[1,2], Dr. Chu-Ping Yu[1,2], Dr. Armand Béché[1,3], Prof. Dr. Jo Verbeeck[1,2]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [3]AdaptEM, Heverlee,, Belgium

IM-04 (1), Lecture Theater 1, august 27, 2024, 10:30 - 12:30

Similarly to Spatial Light Modulators (SLM) in optics, Electron Phase Plates (EPP) have emerged as a promising solution to several challenges in electron microscopy, such as in-focus phase contrast, adaptive tuning, and exotic beam preparation. Our proposed solution to a generalized EPP is based on an array of miniaturized Einzel lenses that can shift the electron wavefront locally. This electrostatic EPP can be positioned in the electron beam's path in a Transmission Electron Microscope (TEM). The supports and interconnections that make up the EPP will inevitably modulate the amplitude of the electron wavefront. However, the EPP also allows one to adjust the shape of the electron wavefront locally by applying a voltage to each phase pixel [1].
This work demonstrates a fully programmable electrostatic EPP of 48 phase-shifting elements mounted in a state-of-the-art TEM [2]. We prove the device's versatility by preparing a set of orthogonal probe shapes and reproducing the influence of specific geometric aberrations (e.g., defocus of a convergent electron probe). Furthermore, we show a fully automated Scanning TEM (S/TEM) routine in which the EPP corrects the aberration function without active user intervention.
Finally, we discuss the device's potential for novel imaging techniques such as electron ptychography. Typically, this technique requires scanning a convergent electron probe over a small area of the sample, which may lead to a limited field of view [3]. Recent research has demonstrated the use of a quasi-parallel beam illumination with both amplitude and phase modulation of the electron wave. By successive shifts of the specimen stage and near-field intensity recording, reconstructions could be performed with a significant expansion of the field of view, with no resolution or electron dose sacrifice [4]. Here, we present reconstruction results obtained through a similar approach for far-field propagation, using different amplitude and phase modulation strategies, as permitted by our programmable EPP design, at different applied electron doses (total dose divided by the number of phase configurations).
The figure below illustrates the far-field ptychographic reconstruction results for three incident electron doses. The illumination on the sample is structured using an array representing the EPP. The columns, from left to right, depict the amplitude mask that is used to simulate the EPP, the phase and amplitude of the object ('Ground Truth'), the results obtained through an amplitude-only modulation ('Flat'), the outcomes of amplitude plus two random phase configurations ('Random'), and the results obtained using a reduced set of two Hadamard phase configurations ('Hadamard').
To summarize, we evaluate our electrostatic EPP in various S/TEM and TEM applications. Our findings indicate that an electrostatic EPP can be integrated into any electron microscopy setup, thereby broadening the device's scope of functions.

Characterisation of Skyrmion Spin Textures in CoB/CoFeB Multilayers

Colin Kirkbride[1], Dr Razan Aboljadayel[2], Dr Kayla Fallon[1], Ms Sara Villa[1], Dr Trevor Almeida[1], Prof. Marrows CH[2], Prof. Stephen McVitie[1]
[1]University of Glasgow, Glasgow, United Kingdom, [2]University of Leeds, Leeds, United Kingdom

Poster Group 1

Background incl. aims
Developing energy efficient data storage requires the discovery of novel materials which can host a variety of high density and controllable magnetic textures. In recent years this has led to an interest in materials capable of supporting magnetic skyrmions owing to their variability in size from several nanometres to microns [1]. In addition, their discrete nature makes them attractive candidates for forming magnetic logic gates, advanced signal multiplexing and neuromorphic computing applications [2]. In this work, we analyse the field dependence of skyrmion spin textures formed in magnetic multilayers of [Ru(7)Pt(X)CoB(4.3)Ru(7)Pt(X)CoFeB(5.3)]15 (all in Å) where X is 8.5Å (S1) or 10.5Å (S2) (Fig.1a). The overall aim is to highlight the importance of Pt thickness on the established spin textures and to motivate these materials as candidates for field controllable skyrmion applications.

Methods
Throughout this work, we utilise a range of microscopic analysis techniques with a strong emphasis on Lorentz transmission electron microscopy (LTEM). All images were acquired using a JEOL JEM-ARM200cF microscope operating in either LTEM or STEM mode equipped with a CEOS probe corrector. Qualitative Fresnel images were captured within a field range of ± 130 mT. Single image transport of intensity (sTIE) reconstructions were used as a method of semi-quantitative magnetic characterisation and supported with more robust differential phase contrast mapping of the integrated magnetic induction at a range of key fields. Topographical and phase characterisation is provided through tapping zero-field MFM and bulk magnetic measurements are analysed with SQUID-VSM. Elemental mappings of multilayer cross-sections are measured using electron energy loss spectroscopy (EELS) and provide layer thickness measurements which aid magnetic volume characterisation.

Results
By comparing the magnetic states of S1 and S2 at a range of fields, we analyse the effects of interlayer coupling within the multilayer. Reducing the applied field from the saturated state above 130 mT, S1 first stabilises a ferromagnetic (FM) skyrmion lattice (SkL) phase which expands into FM domains before forming a second SkL at zero field (Fig.1b). The SkL contrast is then slowly removed as S1 enters a field stabilised synthetic antiferromagnetic phase around -40 mT before the magnetisation switches into a FM domain phase and saturates at high field. We correlate this behaviour with strong coupling between the CoB and CoFeB layers. For S2 the behaviour is markedly different on the reduction of field from saturation. We first form sparsely distributed skyrmions with weak contrast which expand into a FM domain state covering the film. We next form a mixed-phase FM state (Fig.1c) with strong and weak contrast which reduces to a purely strong contrast FM domain state at zero field. Upon field reversal, these FM domains contract to form skyrmions with strong and weak contrast below -100 mT, before proceeding towards saturation. We propose that the varying levels of contrast in S2 are caused by the thicker Pt layer forcing an effective decoupling between the

CoB and CoFeB layers allowing each to act independently in response to applied field. The formation of chiral textures is then driven by the different strengths of interfacial Dzyaloshinskii-Moriya interaction at the CoB/Pt and CoFeB/Pt interfaces [3].

Conclusion
Using Lorentz microscopy, we show that the separation between magnetic layers in CoB/CoFeB multilayers can have a significant impact on the observed magnetic textures. This has important consequences for applications, for example, if one desires a high density skyrmion state at low field (eg: for reservoir computing), then strongly coupled systems, similar to S1, would be useful. In contrast, if sparse skyrmion states are required (eg: for racetrack memories), then decoupled systems such as S2 may be more appropriate. Overall, the work serves as motivation for careful, application specific tuning of layer thicknesses during material growth, and highlights the valuable information that nanoscale magnetic imaging can provide for skyrmion stabilising systems.

IM-06 (2), Lecture Theater 1, august 30, 2024, 10:30 - 12:30

Background incl. aims
The most common method for robust and reliable structure determination of materials is single crystal X-ray diffraction (SCXRD). However, it is not suitable for nanoparticles (NP) and nanodomains due to their size and geometry. When it comes to structural characterization on the scale of a few nanometers, electron microscopy offers an incomparable range of tools. In this contribution, we focus on accurate nanoscale crystallography using electron diffraction and, more specifically, precession-assisted 3D electron diffraction (3D ED), serial ED and scanning precession-assisted electron diffraction tomography (SPET). The aim is to test the limits of these parallel-beam electron diffraction methods for the accurate structure analysis of isolated NP and nanodomains measuring a few tens of nanometers or less.

Methods
For 3D ED on NPs and nanodomains, the first instrumental requirement appears to be the ability to form parallel beams well below 100 nm in size. If you want to collect single-crystal 3D ED data from a 10 nm domain embedded in a matrix, you must work with an electron nanobeam of this size or smaller. When the diffraction volume is greatly reduced, much lower diffracted intensities are expected. In this case, hybrid pixel detectors is a real asset for studying the size limit of NPs or domains for 3D ED experiments. For this work, our experimental setup is based on a JEOL F200 electron microscope equipped with a ASI Cheetah M3 hybrid-pixel detector. Beam precession movement, combined or not with beam scanning, is achieved via a Nanomegas DigiStar unit.

Results
The question of the lower limit of crystal size compatible with accurate structure analysis by 3D ED is briefly addressed with tests carried out on isolated Indium Tin oxide (ITO) and TiO2 nanoparticles around 10 nm in size. Our study provides experimental evidence that the effect of multiple scattering is still present but significantly reduced for tiny crystals. In such cases, it is possible to obtain fairly accurate structure refinements using kinematical approximation only.
Regarding nanodomains, we explore the limitations associated with their size and the extent to which we can track structural changes at a nanoscale. For this, we shall consider an approach that uses an appropriately sized parallel beam to collect ED patterns at different region of interest (ROI). One way to perform such an analysis is to combine a scanning procedure with precession-assisted 3D ED. The area of interest is selected, and the electron beam is scanned across it with the desired step size while collecting the precession-assisted diffraction patterns. Afterwards, the sample is tilted and the scanning procedure is performed again, and so on, obtaining this way a tomography of a 2D space. Eggeman et al. [1] actually exploited a similar approach for analysing the volume and orientation of domains in crystalline Ni-based superalloys, and used the acronym SPET for Scanning Precession-assisted Electron Tomography data acquisition. We extend the use of SPET for the

structure solution and accurate structure refinement of nanodomains. This implies that after the acquisition, we are able to distinguish, and sort accordingly, the diffraction patterns generated by different ROI in the sample. By doing so, several nanodomains of the specimen can be probed without the need of tracking them while tilting, and therefore to perform structure solution and accurate structure refinements of multiple ROI with a single acquisition.
We first demonstrate the usefulness of SPET for accurate structural characterizations of subtle structural changes in a 35 nm thick $PrVO_3$ thin film [2] using a line scan in a direction perpendicular to the film/substrate interface (see Graphic). Second, we take a step forward employing it for the analysis of nanodomains embedded in ceramics [3] using an area scan and show how it is possible to extract 3D ED data corresponding to single domains/ROI from the SPET data stack.

Conclusion
Regarding the possibility to reveal unknown nano-structure, we propose a shift in the paradigm of 3D ED data collection, from a "point" acquisition, focused on a single ROI, to a multidimensional data acquisition method using scanning precession-assisted 3D ED. With this approach it is possible to obtain accurate crystallographic information from multiple ROI at a scale less than 10 nm.

These results were obtained as part of the European project NanED (Electron Nanocrystallography – H2020-MSCA-ITN GA956099).

Multiparametric investigation of bacterial surface structure with correlative atomic force microscopy

Dr. Joan Carles Escolano[1], Torsten Müller[1], André Körnig[1], Thomas Henze[1]
[1]JPK BioAFM, Bruker Nano GmbH, Berlin, Germany

Poster Group 2

Background incl. aims
Atomic force microscopy (AFM) has become an indispensable tool for high-resolution structural analysis of specimens ranging from single molecules to complex biological systems, while simultaneously being able to correlate topography and mechanics at near native/physiological imaging conditions. In turn, the combination with advanced/customized optics leverages the advantages of immunolabelling techniques for truly correlative microscopy. Specifically, the use of a tip-scanning AFM, as compared to a sample-scanning system, enables simultaneous high-resolution correlation experiments with advanced optical techniques. Studying certain Gram(-) bacterial species have attracted a lot of interest recently as model systems for investigating their outer membrane envelope.

Methods
We have applied fast tip-scanning AFM imaging in combination with confocal microscopy to study the surface structure of bacterial species. We have studied the surface structure of E. coli MG1655 bacteria to gain a deeper insight into the supramolecular organization of their outer membrane protein network.

Results
By additionally exploiting full-fledged sample mechanical mapping we can correlate any substructural surface analysis of the layered bacterial specimen with differences in bacterial stiffness. We demonstrate how the application of dual z-actuator tip-scanning AFM imaging can be exploited for instant high-resolution analysis of tall bacterial samples exceeding 1 µm in height. We will also discuss how the combination of high-speed tip-scanning AFM with antimicrobial agents can be used as a tool to study the bacterial envelope in real-time and potentially develop strategies for fighting microbial resistance.

Conclusion
AFM can be successfully applied to correlate high-resolution structural features and mechanical properties of the outer membrane envelope in MG1655 E. coli bacterial species in combination with advanced optical microscopy.

PS-02 (1), Lecture Theater 5, august 28, 2024, 10:30 - 12:30

Increasing temperature properties of materials is a major strategic challenge for the aviation industry. Titanium alloys like the so-called Ti6242 offer excellent specific mechanical strength and good corrosion resistance up to temperatures of around 550°C. On one hand, molybdenum can be added to reduce creep/fatigue effects known as dwell effect [1] but the associated decrease of alpha phase fraction is detrimental to high temperature performances. On the other hand, addition of silicon improves the mechanical properties at high temperature [2] and compensate molybdenum addition. Still, the strengthening mechanism of silicon is still under discussion.
During aging, silicon leads to the precipitation of silicides [3] which could play a role in the strengthening of the alloy. We have characterized the microstructures by complementary electron microscopies to corroborate the relationship between silicides and macroscopic mechanical properties.
In order to characterize the microstructure at different relevant scales, we used SEM and TEM imaging. Despite a good accuracy, the analysis of the planar or projected images revealed that the strong anisotropies of the lamellae microstructure prevents a good description of the silicide population. Therefore, we also performed 3D reconstructions by FIB/SEM (figure a) on the alloys in the aged state to get reliable statistics on the dimensions, shape and organisation of the silicides in the microstructure (figure b). An additional S/TEM study has been used to determine the precipitate structure and chemistry.
Thanks to FIB/SEM reconstructions, volumes containing 4000 precipitates each have been analysed. Results showed that aged Ti6244 alloys host precipitates with an elongated shape and a mean Feret radius of almost 40 nm. Moreover, when the Si content is doubled, the precipitate density increases (+55 %). The analysis of the precipitate organisation, with respect to the Ti matrix orientation, reveals that the precipitates are mainly located in the beta phase and that their nucleation is likely to occur at the interface between alpha and beta. It also showed that two directions of elongation are favored.
A careful analysis by high resolution S/TEM (figure c) reveals that the S2 silicides are semi-coherent and that their composition is close to (Ti,Zr)6Si3 which is not expected with respect to the thermomechanical treatment used and the CALPHAD calculations. The Burgers relationship between both titanium phases and the S2 silicides are clearly defined and explains the two observed variants. Additional TEM observations after creep at high temperature illustrates the role of the silicide in the dislocation anchoring (figure d).
Thanks to combined microscopy techniques, we show that the silicide precipitation plays a key role in the strengthening of the Ti6244 alloys. The semi-coherent structure and the spatial organization of the precipitates suggest that an Orowan mechanism is favored.

Enhanced imaging for serial Cryo-FIB-SEM microscopy of biological samples with fluorescence navigation

Pavel Krepelka[1], Jana Moravcova[1], Jiri Novacek[1]
[1]Central European Institute of Technology, Masaryk University, Brno, Czech Republic

Poster Group 1

Traditional methods for studying biological specimens with volume electron microscopy face two significant hurdles: the complex process of sample preparation, which includes drying and staining with heavy metals and can introduce artifacts, and the difficulty in maintaining fluorescence signals in samples set in resin. In contrast, cryo-FIB-SEM keeps specimens nearly unchanged in a frozen state, streamlining the preparation process, reducing structural distortions, and allowing easier observation of fluorescence. Yet, imaging non-contrasted biological specimens in cryo-FIB-SEM can be challenging due to low signal-to-noise ratios and charging artifacts.

Our research shows that by fine-tuning the imaging conditions, electron exposure, plasma milling parameters and the workflow management, we can greatly improve the quality of the data, speed up the rate of data collection, and capture large volumes of samples with outstanding ultrastructural clarity. This allows us to view all cellular organelles in detail, achieving resolutions as fine as 16nm. An additional advantage of cryogenic imaging is the preservation of the fluorescence signal, which helps in locating cells and guiding the initial trenches in the sample.

With the mentioned improvements, we acquired high-quality cryo-images. We demonstrate the effectiveness of our cryo-FIB/SEM method by reconstructing a segment of a pancreatic INS-1E beta cell, showcasing the workflow's capability to produce high-quality imaging of biological samples.

High-throughput laboratory-based scattering X-ray Tensor Tomography

Azat Slyamov[1], Mr. Adriaan van Roosmalen[1], Mr. Kenneth Nielsen[1], Mr. Erik Lauridsen[1]
[1]Xnovo Technology ApS, Køge, Denmark

IM-04 (1), Lecture Theater 1, august 27, 2024, 10:30 - 12:30

Background incl. aims
Scattering (or dark-field) contrast X-ray microscopy methods for orientation analysis have been gaining increased attention in recent years. The primary advantage of these methods is the ability to map anisotropic structures without directly resolving them, allowing for an extended field of view (FOV). Two different technologies, scanning small-angle scattering and full-field linear grating interferometry have been applied to a wide range of materials, such as fiber-reinforced composites and biological materials [1,2]. However, both methods have disadvantages with throughput: scanning methods have significant overhead in raster scanning the 2D FOV, while gratings require linear and rotational shifts to access 2D orientation sensitivity. A recently developed design of gratings comprised of circular unit cells grid allows single-shot mapping of orientations/scattering in 2D [3]. Each unit cell of the 2D grid provides information on local scattering, emulating raster scanning, while the circular design yields 2D orientation sensitivity, all in a single frame. This is particularly important when 3D scattering tensor information is of interest, achieved by what is known as X-ray tensor tomography (XTT) [4].
Here, we present the capabilities of the state-of-the-art XTT technology based on circular gratings, commercially available on the Exciscope Polaris imaging platform. Notably, we emphasize the simplicity and efficiency of the technology in the laboratory and validate the results against the synchrotron implementation of this technique.

Methods
The sample was prepared using a free-form carbon-fiber injection molding by Addifab, ApS (Fig. 1a). Laboratory and synchrotron measurements were performed on an Exciscope Polaris X-ray microscope and at the TOMCAT beamline, Swiss Light Source, Paul Scherrer Institute, respectively. Different grating design is implemented at two setups: phase-based at the synchrotron and absorption-based at the lab. This is due to the polychromaticity and divergence of the X-ray beam of the lab setup. The latter yields geometric magnification allowing for a detector with larger FOV and pixel size. In both setups, a total of 721 sample poses were collected. A series of 8 tile images at each sample pose was acquired with the phase-grating at the synchrotron setup due to the limited size of the X-ray beam.

Results
Stitching tile images from the Tomcat dataset as pre-processing generated one projection image per pose. Subsequently, both synchrotron and lab-setup datasets were reconstructed using identical algorithms and parameters (Fig. 1b). For validation, reconstructed 3D fiber orientation volumes were registered with affine transformation. The agreement between the two volumes was calculated as an inner product of fiber orientation vectors in each voxel, where values 0 and 1 describe an orthogonal and parallel alignment, respectively. A histogram of the per-voxel inner product (Fig. 1.c) reveals exceptional agreement of the results from two experiments with a mean value of 0.95.

Conclusion

Synchrotron facilities are at the forefront of the development and advancements of 3D X-ray imaging technologies. However, limited user access and a high level of complexity hinder the general use of such large-scale facilities. In this context, we present the capabilities of the state-of-the-art XTT technology with origins at synchrotron that has been successfully transferred into the laboratory environment. The transition of XTT with circular gratings to a commercial imaging platform is presented and validated against synchrotron measurements, revealing a high level of agreement.

Achieving atomic precision 3D reconstructions through Bayesian genetic optimisation

Mr. Tom Stoops[1,2], Dr. Annick De Backer[1,2], Prof. Dr. Sandra Van Aert[1,2]
[1]EMAT, University of Antwerp, , Belgium, [2]NANOlab Center of Excellence, University of Antwerp, , Belgium

Poster Group 1

Background incl. aims
Accurate and precise knowledge of the three-dimensional shape of nanoparticles is critical to understanding their unique properties. High-angle annular dark field scanning transmission electron microscopy (HAADF-STEM) provides a powerful tool for quantitative analysis, allowing the extraction of structural information through atom-counting, where the intensities generated by atomic columns in HAADF-STEM are analysed to count the number of atoms with single-atom precision.
However, reconstructing the 3D structure from these counting results remains challenging. Based on the counting results and the prior knowledge of the crystal structure, we can construct an initial guess of the nanoparticle by placing the columns symmetrically around a central plane. While this can serve as an initial guess, further refinement is imperative to make claims about the structure. In recent years several refinement procedures have been proposed. Molecular dynamics and Monte Carlo methods have been used for energy optimisation but may fall short of an accurate reconstruction by becoming trapped in local minima or deviating from experimental observations. A local minima search algorithm can scan the energy landscape for the best energy minimum but does not consider the finite precision of atom counting, which strongly contributes at lower electron doses.
Methods
The implementation of the Bayesian genetic algorithm can address these issues effectively. In contrast to molecular dynamics-based reconstruction methods, where each atom is individually considered, the Bayesian genetic algorithm is a holistic approach; it incorporates all knowledge obtained from the HAADF-STEM image. The column positions are fixed to the observed locations in the image, and the thickness variations are constrained by the known finite precision of the atom-counting analysis.
The initial guess for the three-dimensional structure created based on the atom-count results and prior knowledge of the crystal structure functions as a reference in the genetic sequence. By encoding parameters such as the height offset and thicknesses of columns with respect to the initial guess, we can describe any possible 3D structure generated by the columns in the observed image. The genetic algorithm will then utilise mutations and combinations of members to optimise a cost function. By generating large populations of candidate reconstructions with genetic variety, the algorithm can effectively scan the local energy landscape for an optimal solution which balances the energy minimisation and atom-counting probabilities.
However, genetic algorithms can become prohibitively computationally expensive for large nanoparticles due to the rapid growth in the number of parameters required to describe their 3D shape. Furthermore, the simulation parameters (population size, mutation density, ...) are difficult to standardise as they may differ significantly for each optimisation problem and genetic algorithm implementation. To this end, we have optimised the algorithm for computational efficiency and proposed simulation parameters which balance the need for mutations with the convergence rate such that the algorithm can reconstruct nanoparticles of up to at least 10 nanometres in size.

Results
Though the computational cost and choice of parameters of genetic algorithms, in general, is a whole area of study by itself, we have explored the behaviour for the specific application of reconstructing the three-dimensional shape of nanoparticles. By choosing appropriate simulation parameters by balancing the mutation rate with the population size, we examine the scaling relationship of the convergence rate as a function of atomic columns in the image. A statistical analysis gives strong indications of a linear and well-behaved convergence rate.
Additionally, we used the algorithm to reconstruct a large simulated nanoparticle of approximately 10 nanometres in three dimensions with a high surface atom recovery. This demonstrates the capacity to reconstruct large nanoparticles with high accuracy and allows us to study the presence of specific surface features in such particles.
Conclusions
We have optimised and studied the performance of the Bayesian genetic algorithm for the reconstruction of nanoparticles at atomic scale with high accuracy. By doing so, we can reconstruct nanoparticles of up to at least 10 nanometres in size.

End-to-end learning of atomic resolution phase-contrast volumes from 4D-STEM measurements

Shengbo You[1], Dr Andrey Romanov[1], Dr Philipp Pelz[1]
[1]Institute of Micro- and Nanostructure Research (IMN) & Center for Nanoanalysis and Electron Microscopy (CENEM), Friedrich Alexander-Universität Erlangen-Nürnberg,, Erlangen, Germany

IM-03 (3), Plenary, august 29, 2024, 10:30 - 12:30

Background incl. aims
Ptychography has been proven to have the ability to efficiently recover phase information of the specimen in the Transmission Electron Microscope (TEM). However, with traditional single slice ptychography, the multiplication assumption requires the specimen to be thinner than a few atomic monolayers. Otherwise, multiple scattering becomes significant, and the algorithm fails to recover even the basic structure. To accurately reconstruct the phase information of a thick sample, we combine electron ptychography and tomography into a single algorithm directly reconstructing a 3D electrostatic potential volume from 4D-STEM tilt-series measurements.
Ptychographic atomic electron tomography was experimentally demonstrated to be capable of imaging atoms in 3D volume, together with contrast improvements[1]. Another successful demonstration to image bulk materials was to combine the multi-slice algorithm with ptychography. This powerful combination is capable of imaging individual atoms at a resolution set by the intrinsic size of the atoms. The combination of the multi-slice algorithm and tomography have also been demonstrated using High Resolution TEM. Even with plane-wave illumination, the atoms were precisely located. Hence, with all the successful demonstration, our aim is to develop a joint reconstruction algorithm, combining the multilisce, tomography, and ptychography for bulk materials with atomic resolution. Our experimental realization is an end-to-end reconstruction process, the 3D structure of the material is recovered directly from the 4D-STEM dataset. In the result, the 3D atom positions can be clearly viewed in all 3 dimensions.
Methods
In the collection process, our method is similar to the ptychographic electron tomography experiment, a focused electron beam raster scan through the bulk specimen with adjacent scan positions overlapped. The electron beam passes through the specimen and then propagates through the vacuum. The detector, which is placed in the far-field with respect to the specimen, collects one diffraction pattern for each scan position. In the reconstruction process, we recover the electrostatic potential of the atoms, which multiplying an electron-charge interaction constant is the projected phase information of the specimen. A series of thin slices of the specimen are reconstructed for each tilt angle. The updates from all the tilt angles are applied to the same 3D volume, instead of integrating after the reconstruction. In other words, the updated volume in the current angle is used in the forward path of the reconstruction of the next angle. In Figure 1 a), the calculated volume is rotated and shifted using affine alignment (A), and then binned (B). The electron beam, with 3 modes and their exit wave shown, passes through the model and forms a diffraction pattern at each scan position. In Figure 1 b), the 4D-STEM datasets update the exit wave at the backward path at each angle, and eventually recover the potential of our model. A regularization kernel is used to reduce the binning effect. Butterworth filter and a modified L1 normalization are used to erase the noise.
Results
We used modal decomposition method to model the partial coherence of the illumination wave. The complex wave transfer function and their positions were reconstructed together with the 3D sample

volume. The sample in our experiment was ZrTe2. The reconstructed electrostatic potential of our sample clearly imaged the individual atoms. The algorithm yielded a high contrast of the core structure, which helped us separate the atoms from the vacuum. A series of hyper-parameters were tuned to test their effects. We also tested the performance of our system under low-dose condition by skipping part of the diffraction patterns.

Conclusion

In summary, we experimentally demonstrated end-to-end reconstruction for ptychographic multi-slice electron tomography is capable of 3D structure determination with atomic resolution. With a series of fine-tuned regularization tools, our joint reconstruction algorithm yields a high SNR volume with contrast improvements. With the low-dose test, the algorithm shows promising potential for imaging beam-sensitive materials such as polymers, battery materials, and biological molecules.

Poster Group 1

Background incl. aims
Perovskite oxide compounds, with the chemical formula ABO3, constitute one of the most studied family of oxides due to its large variety of fascinating properties combined with their high degree of tunability. Although the prototypical perovskite lattice is cubic, additional structural distortions emerge when the ionic size ratio (A/B) deviates from one, thus lowering its symmetry. Among all the possible resulting space groups, the orthorhombic Pbnm lattice is one of the most common ones. For instance, most Vanadates, Nickelates, Iridates and Titanates share these particular lattice symmetries. The anisotropic unit cell of such compounds is characterized by in-phase octahedral rotations about one pseudocubic axis (the long orthorhombic one) and out-of-phase rotations about the other two pseudocubic ones; plus additional relative A-site displacements that feature a zig-zag pattern along the [110]PC direction.
When growing epitaxial heterostructures, the Pbnm lattice may nucleate differently oriented depending on how the unit cell is constrained by its neighboring epitaxial layers. When different orientations are equally energetically favorable, the presence of lattice domains with distinct orientations emerge, which in turn may lead to the presence of crystal defects. Retrieving all of this information is therefore paramount when designing novel heterostructures for electronic devices, as it will affect their resulting physical properties. For instance, improper ferroelectricity in artificial superlattices requires the long orthorhombic axis to be oriented out-of-plane. However, since the three pseudocubic axes are in most of the cases very similar in length, it is typically challenging to extract this information from conventional X-ray diffraction analyses.

Methods
In this contribution, we present a very simple and fast approach devoted to map Pbnm lattice domains.1 It is based on using the conventional geometrical phase analysis (GPA) but in a non-conventional manner. Since the relative zig-zag displacements of the A-site cations double the unit cell length along the long orthorhombic axis, they feature additional half-order reflections in the Fourier Transform (FT) pattern of aberration-corrected STEM images. The strategy behind our methodology consists then on using the conventional aperture settings used for regular strain mapping (centered in the (001)PC and (100)PC or (010)PC reflections), but this time including the {(1/2) 0 1}PC or {1 0 (1/2)}PC reflections within the selected aperture area as well. When these particular aperture settings are used, additional fringes (related to the A-site relative displacements) appear in the exy and rxy maps only in those areas contributing to the emergence of these half-order reflections in the corresponding FT pattern.

Results

As a showcase of the versatility and robustness of this methodology, we further exploit this approach to determine the structural parameters that set the lattice orientation and associated domain distribution in rare-earth nickelate compounds. For this, we have analyze the domain distribution in a series of rare-earth nickelate heterostructures grown under distinct structural constraints. Although we will show that the resulting lattice orientation and domain distribution mainly depends on the in-plane normal epitaxial strain, we will also demonstrate how shear strain and interfacial structural connectivity are also very relevant, and should not be neglected when designing novel heterostructures.1-3
Finally, we will also show that this methodology is not restricted to Pbnm domain mapping, but can also be exploited to identify some specific lattice defects or domain boundaries that are otherwise very challenging to localize. Further, beyond Pbnm compounds, it can be adapted to map other types of structural periodicities from other space groups that also also render half-integer reflections in the FT patterns of STEM images.

Conclusion
To summarize, in this contribution we will first present a fast, robust and versatile methodology that is very useful to map Pbnm lattice domains. Second, we will discuss how we have applied this to identify key structural parameters that influence domain distributions in epitaxially-grown Pbnm compounds. Finally, we will also comment about other possible scenarios where this methodology can be also useful to track and map periodic structural distortions that render half-integer reflections in the FT patterns of STEM images.

Localized, anodic aluminum corrosion phenomena studied with electrochemical liquid phase electron microscopy

Morgan Binggeli Barbey[1], Prof. Vasiliki Tileli[1]
[1]Ecole polytechnique fédérale de Lausanne (EPFL), Lausanne, Switzerland

PS-12, Lecture Theater 2, august 29, 2024, 10:30 - 12:30

Local corrosion is a major concern for structural materials and it remains one of the most difficult defects to detect due to the submicron size of the local corrosion sites and the fact that they can be obscured by corrosion products [1]. The early stages of localized corrosion are the least understood and the most challenging to study as they occur stochastically at the solid-liquid interface on the nanometric scale [2]. With its combination of spatial resolution, temporal resolution, and analytical capability, electrochemical liquid-phase electron microscopy (ec-LPEM) has shown the potential to provide new insights into the understanding of localized corrosion phenomena [1], [3], [4]. Among these, Al corrosion in saline environments is a relatively well-studied phenomenon, allowing comparison of the ec-LPEM results with previous reports [2].

Commercially available transmission or scanning EM (SEM or TEM) stages were used to confine a liquid solution between two micro-electro-mechanical systems (MEMS) chips. To study Al corrosion using ec-LPEM, we have developed in-house microfabricated electrochemical chips containing one Al electrode and two Pt electrodes that can be electrically biased to perform in situ or operando electrochemical experiments. The three fabricated electrodes feature a symmetrical geometry to avoid local current density hotspots [5]. Potentiodynamic and galvanostatic electrochemical experiments were performed in situ for probing the corrosion of Al in chloride-containing electrolyte.

Linear sweep voltammetry (LSV) measurement was performed at a scan rate of 1 mV/s. The recorded electrochemical signal shows a plateau followed by a peak in the recorded current corresponding to the pitting potential. The recorded image sequence shows corrosion events occurring rapidly once the pitting potential is reached. The corrosion kinetics are found to be too fast for the time resolution of LPSEM. Thus, despite their widespread use in bulk systems, potentiodynamic techniques are not the most appropriate for recording localized corrosion phenomena using EM.

To achieve slower kinetics, galvanostatic control by means of chronopotentiometry (CP) measurements was performed at increasing current levels in the SEM. At the very low current of 1 nA, single pitting events were observed, whereas at the high end of the current range (50 nA), the corrosion was found to proceed rapidly with the simultaneous formation of a gaseous byproduct. Measurements performed at 1, 5 and 10 nA showed oscillations in the electrochemical signal, corresponding to the repassivation of the Al substrate with its naturally formed oxide. Two different corrosion shapes were observed: at low current (1, 5, and 10 nA), successive circular corrosion events occurred, whereas, at higher current densities (5, 10, 20, and 50 nA), fractal-shaped degradation occurred. This could indicate a kinetically dependent mechanism of Al corrosion.

The kinetic behavior of the anodic corrosion was calculated from the post-processed sequence of images taken over a 10-minute period. The processing consisted of 3D Gaussian blurring, median filtering, application of progressive image denoising algorithm, and segmentation of the images. This enabled the corroded area of the aluminum electrode to be determined for each image recorded.

The calculated corrosion rates in the intermediate current range of 10 and 20 nA were found to be in good agreement with the theoretically determined oxidation rate of Al within a range of ±10%, indicating the stability of the developed electrochemical system and the minimal effect of electron imaging on the corrosion mechanism.

Galvanostatic measurements at low applied current (5 nA) were also performed in the TEM. The real-time observations reveal that there is a distinct higher brightness that follows the corrosion front. This is indicative of gas formation (most likely H2) at the metal-liquid interface that is trapped during the process. It is noted that the recorded electrochemical signal did not match the one observed at the same applied current in the SEM, most likely due to electron beam-induced effects which are more pronounced at the scale of the TEM imaging.

In conclusion, we report the development of an electrochemical chip containing an Al electrode for real-time corrosion studies using ec-LPEM. Our methodology and findings can be applied to other electrochemical processes involving aluminum working electrodes, such as the cathode side of lithium-ion battery systems.

In-situ SEM Correlated Nanoindentation and Electrical Nanoprobing

Renato Pero[1], Ms. Anya Grushina[2], Mr. Nicholas Randall[1], Mr. Jean-Marc Breguet[1], Mr. Guillaume Boetsch[2]
[1]Alemnis AG, Schorenstrasse 39, 3645,Thun, Switzerland, [2]Imina Technologies, Rte de Montheron 8B, 1053 Cugy, Switzerland

Poster Group 2

Background inlc. Aims
Understanding the electrical properties of materials and devices under mechanical stress is vital for ensuring their safe and reliable operation and optimizing their design. External mechanical perturbations can lead to significant changes in the electric response of semiconductor devices and functional materials. This presentation introduces a pioneering investigation into the dynamic relationship between mechanical stress and electrical properties, utilizing an integrated in-situ scanning electron microscope (SEM) platform for nanoindentation and electrical nanoprobing. The aim is to address the intricate interactions between mechanical stress and electrical behavior in various materials and devices, particularly focusing on those too small for traditional optical microscopy.
Methods:
The study tackles the complex challenge of probing electrical responses (typically within a current range of 10µA-10mA) during nanoindentation experiments (with typical load ranging from 100µN-4N and displacement from 0.1nm-40µm), requiring the high-resolution environment of an SEM. The methodology extends to investigate scenarios where mechanical deformations are induced by electrical biasing, offering a comprehensive understanding of the interplay between mechanical and electrical stimuli. This integrated system is versatile, applicable across diverse domains such as piezoresistive or piezoelectrical structures, nano- and micro-electromechanical systems (NEMS and MEMS), fatigue testing of integrated circuits (ICs), and failure analysis of samples.
Results:
The study showcases the versatility of the integrated in-situ SEM platform in investigating the dynamic relationship between mechanical stress and electrical properties in various materials and devices. It presents case studies including a comprehensive analysis of the mechanical stress response of PtCr metal lines and the characterization of a piezoresistive atomic force microscopy (AFM) cantilever. These case studies offer insights into material behavior under mechanical stress and provide valuable information for the design of robust electronic applications.
Conclusions:
The presented integration of nanoindentation and electrical nanoprobing within an SEM environment offers a promising avenue for advancing the understanding of material behavior under combined mechanical and electrical stimuli. By addressing the challenges of probing electrical responses during mechanical testing, this approach provides valuable insights into the behavior of materials and devices, contributing to the optimization of their design and enhancing their reliability and performance in various electronic applications.

In-situ Extreme Mechanics – Recent Innovations and Prospects

Mr. Nicholas Randall[1], Renato Pero[1], Mr. Jean-Marc Breguet[1]
[1]Alemnis AG, Schorenstrasse 39, 3645,Thun, Switzerland

Poster Group 2

Background inlc. aims:
In situ scanning electron microscope (SEM) micro- and nanomechanical testing has become essential for materials design and fundamental mechanics research. Traditional nanoindentation techniques have expanded to include new protocols and testing geometries, allowing for the exploration of microstructure–property relationships, intrinsic material behaviors such as orientation-dependence and plasticity, fracture dynamics, and the performance of innovative micro-3D-printed metamaterials. This versatile technique contributes significantly to various scientific domains, including thin films, coatings, metallurgy, glasses, ceramics, nuclear, semiconductors, biomechanics, and architectured materials. Conducting micromechanical tests within a SEM offers distinct advantages, such as unparalleled control, stability, and positioning accuracy, as well as the ability to perform unique correlative experiments by integrating mechanical data with direct imaging or electron backscatter diffraction (EBSD) measurements and focused ion beam (FIB) techniques. This study aims to present the recent developments in instrumentation for in situ extreme mechanics testing at the micro and nanoscales. Specifically, it focuses on a testing platform capable of strain rate-dependent testing across a broad range, from 0.0001 s-1 up to 10,000 s-1 (spanning 8 orders of magnitude), while offering simultaneous high-speed actuation and sensing capabilities with resolutions at the nanometer and micronewton levels, respectively. Additionally, the study addresses the challenges and solutions associated with performing extreme micromechanical tests over a temperature range from -150°C to 1000°C, highlighting the inherent advantages of utilizing small sample volumes.
Methods:
The instrumentation discussed in this study encompasses a sophisticated testing platform designed for extreme micromechanics. It incorporates advanced capabilities for controlling strain rates and temperatures while enabling high-speed actuation and precise sensing. The methodology involves detailed experimental setups tailored to accommodate the diverse range of extreme conditions, ensuring accurate and reliable data acquisition during in situ testing within the SEM environment.
Results:
The study demonstrates the efficacy of the developed testing platform in conducting in situ extreme mechanics experiments at the micro and nanoscales. By showcasing examples of such tests, it highlights the platform's ability to explore material behaviors under various extreme conditions, including high and low temperatures, dynamic loading scenarios, and different strain rates. The results illustrate the platform's versatility and reliability in capturing crucial mechanical data with high resolution and accuracy, paving the way for comprehensive understanding and analysis of material responses under extreme environments.
Conclusions:
In conclusion, the presented advancements in instrumentation for in situ extreme mechanics testing offer valuable insights into the mechanical behavior of materials at the micro and nanoscales under extreme conditions. The study underscores the significance of employing such techniques to address diverse scientific and engineering challenges, ranging from high-temperature applications in engines to cryogenic environments in hydrogen storage. Moreover, it emphasizes the potential for future

research endeavors to further explore and expand the capabilities of extreme micromechanical testing, thereby driving innovations in materials science and mechanics.

MIPAR Spotlight: Shedding Light on Next-Generation Detection for Microscopists

CEO Sammy Nordqvist[1], Mr Sammy Nordqvist[2], Dr John Sosa[1], Mr Michael Kudlinski[1]
[1]MIPAR Image Analysis Software, Columbus, United States, [2]SciSpot, Stenungsund, Sweden

Poster Group 2

Background
For scientists and engineers across various disciplines, image analysis serves as a vital tool for gaining deeper insights into complex phenomena. Whether studying biological structures, geological formations, engineering components or materials microstructures, the ability to extract quantitative data from images is invaluable. Image analysis enables engineers and researchers to replace manual analysis and increase productivity, to gain additional data insights and improve statistics, and to advance their work by solving complex problems. By harnessing the power of image analysis, scientists and engineers can accelerate research, optimize manufacturing processes, and improve performance of products across a wide range of fields, ultimately advancing our understanding of the natural world and improving technology.

Method and results
Using deep learning and powerful image analysis engines, MIPAR (www.mipar.us) allows users to perform a fast, accurate and automated analysis of images. Through a user-friendly interface, engineers and researchers can personalize analysis to their samples as well as visualize and extract measurements - all without programming. Through five integrated applications, MIPAR offers flexibility and efficiency for 2D and 3D analysis applications. The key ingredients are in the Recipes, which include a series of analysis steps that are tailored to each application. As a result, researchers and engineers can now easily solve problems such as grain size analysis excluding the twins, particle analysis of clusters, defect identification and many more.

Seamlessly integrated within the MIPAR ecosystem, the Snap tool, powered by Spotlight, offers accelerated creation of training datasets for an efficient and streamlined model training workflow. The accurate segmentations provided by Spotlight allow for less time spent creating models and algorithms, leading to faster data collection. MIPAR Spotlight simplifies image analysis even further by limiting the need for custom model configurations and amplifying a model's ability.

Conclusion
This presentation will overview the advantages of using MIPAR Spotlight, the new cutting edge of detection, to analyse grains, particles, droplets, and defects with real industrial applications.

Enhancing quantifiability of S/TEM-based composition mappings through correlative techniques

Kai-luis Jakob[1], Mr. Frederik Otto[1], Dr. Dirk Berger[2], Dr. Tore Niermann[1], Prof. Dr. Michael Lehmann[1]
[1]Technische Universität Berlin, Institute of Optics and Atomic Physics, Berlin, Germany, [2]Technische Universität Berlin, Zentraleinrichtung Elektronenmikroskopie (ZELMI), Berlin, Germany

Poster Group 2

Background incl. aims
In the realm of semiconductor physics and material engineering, the precise quantification of alloy concentrations is imperative as slight variations in the concentration can have far-reaching implications for the optical and electrical properties of semiconductor devices, e.g. InGaAsN near-infrared lasers [1]. As humanity continuously advances the frontiers of nanotechnology and device sizes shrink to just a few atomic layers, material's analysis must keep up and provide sufficient precision in the determination of alloy concentrations as well as the necessary spatial resolution to resolve these tiny devices. While S/TEM based approaches provide this necessary spatial resolution, each method used to determine elemental concentrations in STEM presents its own challenges, especially when it comes to quantifiability. To reliably determine concentrations, STEM-EDX for example, relies on proper reference samples and detailed knowledge of the systems x-ray signature [2]. Diffraction based techniques, such as dark-field imaging of a chemically sensitive beam, exhibits strong dependencies on the specimen's thickness and bending, as these influence dynamic diffraction conditions [3].
The study aims to improve the accuracy of compositions mappings by leveraging the individual challenges and advantages of EDX and diffraction-based techniques against each other.
Methods
We prepare a TEM-lamella, incorporating InGaAs layers (with known In concentration) near the [100] foil normal, employing classical cross-section preparation. This specific zone axis, characterized by 4 {002} reflections, exhibits chemical sensitivity as the structure factors of these {002} reflections hinge on the difference in atomic scattering factors within the unit cell of constituent materials. To exploit this chemical sensitivity optimally, we strategically tilt the specimen, predominantly exciting one of these reflections. This minimizes dynamic diffraction effects while concurrently enhancing the relative intensity of the respective reflection.
Employing an ultrafast pixelated detector, we systematically scan the tilted specimen, capturing 2D diffraction patterns. In a complementary set of measurements, STEM-EDX signals from the layer are acquired for a comparative analysis. STEM-EDX measurements and 4D-STEM mappings are conducted on a JEOL ARM300F2 at 300kV with a 2.2 sr EDX-system. The integration of these measurements is achieved through 2D cross-correlation of the simultaneously acquired signals on the HAADF detector. Subsequently, virtual dark-field image of the (002) reflection is computed, facilitating a direct correlation with the structure factor and, consequently, revealing the corresponding Indium concentration within the layer. Results are compared to Bloch waves simulations to account for dynamic diffraction effects for the respective lamella thickness. Further investigations of the Indium segregation are conducted in high-resolution conditions analyzing the geometric phase.
Results
From a dark-field image of the (002) reflection, a segregation profile for the Indium concentration within a 5 nm layer of InGaAs, nominally possessing a 20% indium concentration, can be extracted.

It's noteworthy that, for the specified indium concentration and under strong-beam conditions, no significant disparity in indium levels, attributable to dynamic diffraction, is noticeable when comparing the (020) and (002) reflections. In Fig. 1 a segregation profile of the Indium concentration with a Muraki-Fit [4] is shown. Furthermore, for small Indium concentrations, the dependency of the concentration determined by this dark-field imaging on the specimen thickness seems to be negligible. This assertion finds support in Blochwave simulations, analyzing dynamic diffraction. For larger Indium concentrations, strain effects play an increasingly important role in the analysis of concentrations through dark-field imaging. Here, we explore the possibilities of determining concentration profiles from strain analysis, taking into consideration strain relaxation at the lamella surfaces. The obtained results are compared to STEM-EDX mappings of the same quantum well layer. Our comprehensive discussion covvers the results and their implications for the interplay with specimen thickness, Indium segregation, and how these factors collectively impact spatial resolution and quantifiability in STEM-EDX. In further investigations, we replicate the study using a set of TEM specimens prepared through a FIB TEM-lamella preparation. This replication aims to scrutinize the influence of FIB Ga-ions on the composition determination in Ga-based heterostructures, the changes to the In-distribution and amorphized layers.

Conclusion

Among the multitude of interaction possibilities of the high-energy electron beam, traditional approaches often focus on a single interaction, such as analyzing the corresponding x-ray signature of the specimen. However, scanning transmission electron microscopy techniques provide a broader perspective, as the transmitted electrons carry additional information for each scan position. This interplay becomes particularly valuable dealing with diverse measurement conditions, including specimen thickness and orientation, providing an opportunity to enhance the quantifiability of composition mappings. Importantly, this methodology transcends the limitations of individual techniques, leveraging the improved signal-to-noise ratio for thicker specimen in EDX over diffraction-based techniques, which are more effective with thin specimens. The resulting versatility not only enables precise composition determinations across a wider range of specimen parameters but also reveals additional synergies. For instance, it aids in resolving the indium concentration degeneracy in a pure analysis of the local form factor for InGaAs quantum devices. These insights not only amplify the quantifiability of S/TEM-based composition mappings but also harmonize well with novel approaches of composition determination, such as the analysis of stress relaxation for thin TEM-lamellas.

Confined single-molecule imaging by low-dose electron microscopy

Huiqiu Wang[1,2], Prof. Xiaodong Zou[1]
[1]Department of materials and environmental chemistry, Stockholm University, Stockholm, Sweden,
[2]Department of chemical engineering, Tsinghua University, Beijing, China

Poster Group 2

Single-molecule imaging with atomic resolution is a notable method to study various molecular behaviors and interactions. Although low-dose electron microscopy has been proven effective in observing small molecules., it has not yet helped us achieve an atomic understanding of the basic physics and chemistry of single molecules in porous materials, such as zeolites. The configurations of small molecules interacting with acid sites determine the wide applications of zeolites in catalysis, adsorption, gas separation, and energy storage. Here we report the atomic imaging of single pyridine and thiophene confined in the channel of zeolite ZSM-5. Based on integrated differential phase contrast scanning transmission electron microscopy (iDPC-STEM), we directly observe pyridines or thiophenes' adsorption and desorption behaviors in ZSM-5 under the in situ atmosphere. The adsorption configuration of a single pyridine or thiophene is atomically resolved and the S atoms in thiophenes are located after comparing imaging results with calculations. The strong interactions between molecules and acid sites can be visually studied in real-space images.

Exploring novel joining technique of Gas Actuated Bonding by utilizing In-situ Environmental-TEM

Dr. Rahul Bhattacharya[1], Dr. Martin Ek[1], Dr. Filip Lenrick[1]
[1]LTH, Lund University, Lund, Sweden

PS-02 (1), Lecture Theater 5, august 28, 2024, 10:30 - 12:30

Background
The reliability of a critical industrial component is decided by the durability of the weakest joint or spot. For applications involving high-temperature operational conditions especially coupled with corrosive environments like fuel cell interconnections, molten metal baths, etc., the joints are the most vulnerable regions for catastrophic failure due to localized material degradation by selective corrosion leading to compromised mechanical behavior. The existing joining techniques lead to a continuous metallic phase with modified microstructural characteristics at the bridging junctures or employ a joining alloy that integrates two parent materials. These bridging phases are proving to be the weakest points of the components because they are prone to corrosion compared to parent materials. This is effectuated by the microstructural transformation as well as local compositional fluctuation incorporated in the bridging phases as a consequence of the joining techniques and procedure currently in use.
On the other hand, the semiconductor industry utilizes emerging brazing technologies built on well-established Chemical Vapor Transfer (CVT) technologies (e.g., CVD, MOVPE, PVD). Even though both oxide removal and metal migration into the gap are crucial in metal bonding, there is only one published concept for delivery of non-metallic MPD [1], and a few studies of utilizing active gases for oxide removal.

Methods
The methodology of GAB requires the joints to be made from the bulk material itself by utilizing both gaseous oxide removers (OXR) and gas phase melting point depressants (MPD). In transient liquid phase (TLP) diffusion bonding, a method that lies between brazing and diffusion bonding, diffusion is sped up by a metal MPD interlayer. The preparation of superalloys or the brazing of Al-alloys has been conducted by the oxide removing technology which is contemporarily in practice. This process resulted in the best possible corrosion resistance and strength because both the joint and the bulk have obtained a similar surface oxide and microstructure. Furthermore, by introducing melting point depressing gases on metal surfaces, GAB induces a transient liquid phase similar to chemical vapor transport (CVT) technology. The two critical rate-determining steps in GAB are the removal of the pre-existing surface oxides of the nanoparticles and metal migration into the gap corresponding to the effect of temperature of exposure and partial pressure of the MPD precursor gas.

Results
GAB of pure Cu has been studied in-situ Environmental Transmission Electron Microscope (E-TEM) from a nanometer-sized AgCu particle. Temperature was held constant at 520°C, where the particle is identified as solid. After gaseous AsH3 is allowed to flow into the chamber, the particle is observed to alloy with As and is then identified as liquid (without any temperature change). Similar trials are attempted on 316L steel nanoparticles in experiments conducted utilizing a similar setup of in-situ E-TEM wherein GAB is obtained by melting point reduction using phosphine (AsH3). Therefore, we have built upon the well-established Chemical Vapor Transport (CVT) technology to induce a

transient liquid phase that could form joints with greatly enhanced mechanical and anti-corrosion properties. This leads to a novel metal joining technology called Gas Actuated Bonding (GAB) wherein melting point depressing (MPD) elements are transported as MPD-precursor gas to the joining zones. This takes place during processing to initiate surface reactions that create a liquid transition phase. This will lead to a profound improvement in the quality and consistency of the bridging phase in terms of microstructural consistency, thermal stability, along with enhanced mechanical properties.

Conclusion
Miniature components can be effectively assembled utilizing GAB by circumventing the need for obstructive fillers through the use of MPD-precursor gases that particularly actuate the outermost surfaces. Thus, heat-affected zones and deformation are subsequently prevented. This further validates GAB as a highly suitable manufacturing technology for such small and complex components. Hence, we can observe a drastic improvement in performance as the joints and bulk will have homogeneous surface oxides and homogeneous microstructure. The GAB mechanism is thus thoroughly investigated and understood by in-situ E-TEM experiments at various partial pressures of the MPD gases and the temperature of in-situ heating.

Graphic description
Preliminary results from GAB of AgCu. a) Schematic illustration. b) Elemental mapping in E-TEM. A nanometer-sized particle of AgCu is observed to be solid at 520°C in a vacuum. When AsH3 is flowed into the chamber the particle alloys with As and melts. c) Isothermal Section of the Ag-As-Cu Ternary Phase Diagram at 500°C. 3D Investigation of Lath Martensite in a Low-Carbon Stainless Steel Using PFIB-EBSD Tomography

Mehdi Mosayebi[1], Mr Daniel Paquet[2], Mr Pierre-Antony Deschênes[2,3], Mr Laurent Tôn-Thât[2], Dr Nabil Bassim[1,4]
[1]Materials Science and Engineering Department, Hamilton, Canada, [2]Hydro-Québec, Hydro-Québec Research Institute, Varennes, Canada, [3]Mechanical Engineering Department, École de technologie supérieure, Montreal, Canada, [4]Canadian Centre for Electron Microscopy, McMaster University, Hamilton, Canada

Poster Group 2

Background
Lath martensite in steel is well known to be tremendously complex due to a hierarchical microstructure consisting of packets, blocks, sub-blocks, and laths [1]. The complexities arising from this spatially varying and multi-scale microstructure, have effectively hindered the analysis associated with lath martensite. 3D characterization techniques have demonstrated great potential to provide important insights into the 3D morphology of complicated microstructures [2]. In this regard, serial section tomography with Xe+ plasma focused ion beam (PFIB) offers the ability to collect data from sufficiently large volumes to be statistically representative of the bulk material while maintaining sufficient spatial resolution to observe all relevant features of a complex microstructure [3]. Accordingly, this study aimed to employ electron backscatter diffraction (EBSD) technique in conjunction with high-precision and large field-of-view PFIB serial sectioning tomography in order to enable a full identification of the microstructural elements in a lath martensitic structure.
Methods
The material used in this study was an as-quenched low-carbon 13Cr-4Ni martensitic stainless steel. Block-lift-out and U-shaped trench techniques were used to prepare large cross-sectional volumes using TFS Helios G5 PFIB and ZEISS Crossbeam 350 laserFIB, respectively (Figure 1). An automated routine of serial slicing and subsequent EBSD data acquisition were then performed using the Auto-Slice-and-View 4.0 software. Reconstruction steps including the importation of the raw data, thresholding, alignment, clean-up, and segmentation were all carried out in DREAM.3D software. Following reconstruction and segmentation, the final 3D dataset was visualised using ParaView software.
Results
Figure 2(a and b), display the reconstructed 3D volume of the martensitic microstructure in the form of Euler angle and band contrast maps. Martensitic blocks were segmented manually (i.e., using the specific FeatureIDs assigned by DREAM.3D), and then reconstructed in 3D as shown in Figure 2(c-j). Crystallographic analyses revealed that each prior austenite grain (PAG) can be decomposed into clusters of martensitic blocks, namely packets, such that blocks with specific variants can adopt unique morphological arrangements in 3D. Figure 2(c-f) showcase examples of these morphological arrangements including: (i) parallel arrangement of three distinct variants sharing 60°@[011] orientation relationship, (ii) T-shape arrangement of two distinct variants sharing 10.5°@[011] orientation relationship, and (iii) Triangular arrangement of three distinct blocks sharing 10.5°@[011], 49.5°@[011], and 60°@[011] orientation relationships.
The presence of numerous blocks/platelets with various crystallographic and spatial orientations, leads to many opportunities for the martensitic features to meet at different locations and thereby forming complicated networks in 3D. Here we used the acquired morphological information to

confirm the physical contact between the martensitic blocks within the volume of the PAGs (Figure 2(g and h)). This was further combined with the crystallographic information (e.g. crystallographic misorientations between the blocks in Figure 2 (d)), to reconstruct the boundary networks in 3D. As an example, Figure 2(i and j) illustrate 3D perspectives of the boundaries corresponding to 2 different packets and their blocks delineated by a black rectangle in Figure 2(g). 3D observations suggested a significant morphological difference between the packet boundaries (strip-like morphology) and block boundaries (flat surface morphology) within the lath structure of the martensitic stainless steels (Figure 2(i and j)).

Conclusions

Martensitic features including blocks, packets, and their boundaries were analyzed in 3D. Three distinct configurations, including (i) parallel arrangement, (ii) T-shape arrangement, and (iii) Triangular arrangement, were identified for the martensitic blocks depending on their crystallographic variants. Two different morphologies, (1) strip-like morphology, and (2) flat-surface morphology, were also observed for the packet boundaries and block boundaries, respectively.

Determining alloy concentration by analyzing dynamic diffraction at strained semiconductor interfaces

Frederik Otto[1], Dr. Laura Niermann[1], Dr. Tore Niermann[1], Prof. Dr. Michael Lehmann[1]
[1]Technische Universität Berlin, Berlin, Germany

Poster Group 2

Background incl. aims
In the realm of semiconductor devices, particularly in the context of quantum well lasers, the optical properties are shaped by bandgaps and band offsets derived from precisely engineered alloy concentrations in ternary semiconductors, exemplified by InGaAs quantum wells in GaAs. While S/TEM possesses the necessary spatial resolution for resolving sharp interfaces, EDX typically lacks precision in determining the alloy concentration. However, during epitaxial growth on a substrate, lattice mismatch induces stress at the interface, resulting in localized lattice deformations known as strain. When preparing a thin transmission electron microscopy (TEM) lamella of a strained interface, the stress supporting this strain lacks support on the top and bottom of the lamella, leading to stress relaxation. For a compressively strained layer, this corresponds to the lamella bulging outwards at the interface. The magnitude of this relaxation is unique to the strain at the interface cause by the lattice mismatch, and hence by the alloy concentration in the layer.
The aim of this study is to deduce the alloy concentration of compressively strained InGaAs quantum wells in a GaAs matrix through a detailed analysis of stress relaxation at the lamella's surfaces. This is accomplished by evaluating patterns inside the diffraction discs using scanning convergent electron beam diffraction (SCBED). These patterns, manifestations of multiple electron scattering or dynamic diffraction, exhibit high sensitivity to small changes in displacement in electron beam direction and consequently, to stress relaxation at the lamella’s surfaces. Alloy concentrations are determined by matching beam simulations of relaxed lamellas with varying parameters to the experimental data.
Methods
We prepare a TEM-lamella containing InGaAs layers with known In-concentration in GaAs close to the [100] zone axis using FIB. Deriving information involves detailed reproduction of measured features through simulations to infer the original lamella state. For computational efficiency, we tilt specimen along a quantum well layer into [002] systematic row conditions. Full 2D diffraction patterns (256x256 pixels) are recorded at each scan position within a 256x256 scan window. The resulting 4D dataset can be reduced to a 2D-representation, named as x-q plot, by considering the problem’s symmetry. This reduction involves focusing on one spatial coordinate x orthogonal to the layer. Additionally, only one reciprocal coordinate q along the systematic row, into which the specimen was tilted, is considered. The convergence angle is chosen to achieve non-overlapping discs.
To model the experimental data in simulations, we employ a two-step forward calculation process: Initially, we model the initial stress and the resulting relaxation by doing finite element calculations, providing the layer width, elastic constants and lattice mismatch as inputs. The resulting displacement is then incorporated into beam simulations, numerically propagating the Darwin-Howie-Wheelan (DHW) equation. The simulations are fine-tuned to align with experimental conditions, accounting for tilt, specimen bending, and lamella thickness.
Results
Leaveraging the nominal alloy concentration of a 5 nm wide In0.23Ga0.77As quantum well within GaAs, we successfully replicate dynamic diffraction features in simulations, yielding three key

outcomes, as illustrated in Fig. 1. Firstly, our measurement reveals distinct features discernible in the x-q plot, unveiling changes in dynamic diffraction, even at considerable distances of multiple quantum well widths from the interface (Fig. 1 a). Secondly, comparing these findings with DHW beam simulations that omit surface relaxation highlights the absence of these long-ranging features, conclusively attributing them to surface relaxation (Fig. 1 b, c). Lastly, by manipulating the initial lamella alloy concentration, we can modulate the influence of surface relaxation. Minimizing the discrepancy between the measurement and simulations for the Indium concentration allows us to faithfully reproduce the nominal Indium concentration. These results are validated using STEM-EDX and dark-field imaging of a chemically sensitive reflection. We further discuss the method's limitations concerning specimen thickness, quantum well width, and alloy concentration.

Conclusion

Our study successfully identifies the nominal alloy concentration of a compressively strained InGaAs quantum wells in GaAs through a detailed analysis of stress relaxation at the TEM-lamellas surfaces. This accomplishment involves precisely replicating dynamic diffraction features within diffraction discs through simulations. These simulations account for surface relaxation by incorporating the displacement from finite-element calculations of the strained interface for a given specimen thickness. The process of minimizing discrepancies between measurement and simulation by adjusting the alloy concentration opens a novel avenue of discerning semiconductor alloy concentrations at strained interfaces by analyzing the impact of surface relaxation on dynamic diffraction.

Poster Group 2

Background incl. aims
Topological defects in ferroic materials are important in solid state physics since they can exhibit different intrinsic properties from the bulk and act as active sites in device engineering.[1] Investigation of those defects in terms of their structural variations and relevant properties in special materials systems opens a new path for improving materials' performance and developing novel devices. Here, we aim to investigate the structural and electronic properties of the ferroelastic domain wall in a well-known visible-light catalytic material,[2] monoclinic scheelite $BiVO_4$ (ms-BVO), which may be interesting for photochemistry-relevant applications.

Methods
The BF-TEM image and SAED were obtained using a JEOL JEM-F200 S/TEM operated at 200 kV for domain wall determination. HAADF-STEM images and electron energy loss spectroscopy (EELS) were obtained using a JEOL Grand ARM300F2 double-corrected S/TEM operated at 300 kV, for atomic resolution crystallographic structure and electronic structure demonstration. A Digital Instruments Nanoscope-IV Multimode atomic force microscope equipped with a c-AFM application module (TUNA) was used for nanoscale conductivity measurement.

Results
Highly dense twin walls are found in ms-BVO single crystal and identified as ferroelastic W' wall forming along the strain direction.[3] Opposite shear strain is seen in ferroelastic twin domains (A and B) and released at the wall. The W' wall has a kink configuration, and the overall wall width (d) is approximately ~2 unit cells. The W' walls show clear electrical conductivity by c-AFM under a DC tip voltage of −9.8 V while the domains show no obvious current signal. Subsequent STEM-EELS analysis shows that the V eg state of the W' wall shifts downward of 0.12 eV, indicating a lower conduction band minimum (CBM) compared to twin domains. The larger energy splitting at V L_3 and L_2 peaks at the W' wall is consistent with the symmetry of the topological defects. The higher V L_3/L_2 peak ratio indicates a lower oxidation state of vanadium, i.e., a higher density of oxygen vacancies at the W' wall. The higher shoulder peak at ca. 517 eV (compared to V eg state) indicates the possible accumulation of small polarons at the W' wall. The lower conduction band minimum, increased amount of oxygen vacancies and small polarons may be the reasons for the ferroelastic W' wall conductivity.

Conclusions

The present work investigates the structures and electronic properties of the ferroelastic W’ wall in ms-BVO bulk crystals. The W’ wall is atomically sharp in a zig-zag shape. Compared to non-conductive domains, the W' walls show conductivity in c-AFM measurement under negative bias. The electronic structures revealed by EELS spectra show that the wall has a relatively lowered conduction band minimum, a higher density of oxygen vacancies and possible accumulation of small polarons compared to the domains, which may contribute to the increased wall conductivity. Since the photocatalytic performance of a semiconductor is highly related to its conductivity,[4] the investigation of W' wall conductivity of ms-BVO crystals may help in designing highly efficient catalytic materials.

Electron Videography and Machine Learning of Soft Matter

Prof. Qian Chen[1], Lehan Yao
[1]Department of Materials Science and Engineering, University of Illinois, Urbana, United States

IM-10 (1), Lecture Theater 3, august 29, 2024, 10:30 - 12:30

Background
New methods of materials synthesis and processing with various accelerated discovery strategies have led to huge libraries of functional materials systems. Examples include morphology-controlled nanoparticles as catalysts, nanoparticle superstructures as metamaterials, polymer films with multiscale porosity as separation membranes, to composite energy storage systems. These materials are spatiotemporally heterogeneous in composition, structure, and function, which call for three aspects of advancements in materials characterization. The first is the need for real-space, non-ensemble averaged characterization methods which map the heterogeneity, at least in space, and if possible, over time to capture changes during the synthesis, application, and functioning of materials. The ever-improving toolbox of electron microscopy can meet this requirement by providing atomic to nanometer resolution mapping of the composition, structure, and phase of nanomaterials. Yet, depending on the specific materials systems, different factors still need to be considered in the imaging protocols, such as beam sensitivity, substrate effect, and in-situ stimulation. The second is the need for descriptors to describe heterogeneity. For example, low-dimensional descriptors of symmetry and lattice constants for crystalline solids do not apply for random, or mixed phase systems. Even when it comes to merely the shape (not composition or microstructure), in three dimensions (3D), irregular shapes can be hard to quantify. The third is the need for automated data analysis and reduction methods as high volumes of multi-modal experimental and simulation data are required to describe the heterogeneity and infer the structure–property relationship. Specific to electron microscopy studies, with the cutting-edge detectors, the data collected in one single in-situ experimental session can be 100,000 frames which are extremely laborious to be analyzed manually, let alone the introduction of human bias in the manual analysis process. Mapping properties such as composition and modulus at a similar resolution will only further increase the volume and dimension of the datasets.

Here we will discuss our group's efforts on developing different machine learning strategies to accommodate the data analysis requirements for two different electron microscopy methods, liquid-phase transmission electron microscopy (TEM) and electron tomography, both involving taking series of images and thus referred to collectively as "electron videography". Several materials applications will be discussed, including nanoparticle reaction, self-assembly, and polymer membranes.

Methods
We first introduced the method of U-Net based segmentation for liquid-phase TEM videos1. For liquid-phase TEM videos, they are usually of low signal-to-noise ratio, and thus make manual annotations difficult. To address this challenge, we devised a workflow to generate simulated liquid-phase TEM videos, where the noise levels were captured as dependent on the dose rates to maximally mimic the practical experimental complications. These simulated liquid-phase TEM videos were used as training datasets for the U-Net, with well-defined ground truth, and thus can enable high fidelity and high throughout training of the U-Net, to be used for practical experimental liquid-phase TEM videos.

As to quantification of complex morphologies, we defined a mathematical fingerprint function2 that considers all the coordinates in the shape contours (two-dimensional or 3D) but stays as a one-dimensional function, which can be used as input for principal component analysis (PCA) and then for machine-learning based Gaussian mixture model for grouping of different morphologies and yield analysis. This method works both for TEM images of nanoparticles and electron tomographs of polymer membranes.

Lastly, to facilitate high throughput electron tomography of complex materials3, we developed an unsupervised sinogram inpainting for nanoparticle electron tomography (UsiNet) to correct the missing wedge effects. UsiNet is the first sinogram inpainting method that can be realistically used for experimental electron tomography by circumventing the need for ground truth.

Results
For the U-Net based segmentation of nanoparticles in liquid-phase TEM videos, we were able to achieve high throughput analysis of the nanoparticle reaction kinetics, self-assembly dynamics, and internanoparticle potentials through the statistics accumulated from the liquid-phase TEM videos. For the application of fingerprint functions, they were useful to differentiate the desired tetrahedral nanoparticles from impurities, enabling yield analysis and the investigation of reaction mechanism. They were also capable of differentiating nanoparticles of different patterned polymer coatings, as well as membranes of four different shape categories, which aid the understanding of synthesis-morphology-property relationship. As to the UsiNet method, we apply it to experimental tomographs, where >100 decahedral nanoparticles and vastly different byproduct nanoparticles are simultaneously reconstructed without missing wedge distortion. The reconstructed nanoparticles are sorted based on their 3D shapes to understand the growth mechanism.

Conclusion
We show collectively the usage of machine learning to liquid-phase TEM and electron tomography for understanding the dynamics and synthesis-morphology relationships of complex materials. The experimental and analysis workflow can extend to other in-situ studies of time-series and tomography studies of complex materials, as well as the potential integration of liquid-phase TEM with electron tomography to study 3D morphological evolution of materials important for applications in self-assembly, nanoparticle synthesis, polymer morphing, and energy storage and conversion.

High-resolution STEM Image Acquisition Method for Tilted Specimen Using a New Type of Aberration Corrector

Wataru Koibuchi[1], Mr. Ryusuke Sagawa[1]
[1]JEOL, Akishima, JAPAN

IM-04 (1), Lecture Theater 1, august 27, 2024, 10:30 - 12:30

When acquiring scanning transmission electron microscope (STEM) images, it is necessary to align the crystalline zone axis of a specimen tilt with a goniometer and a holder. Since the backlash and drift cannot be avoided in such operations, it is necessary to wait for the drift to settle after aligning crystalline zone axis for a high-quality image acquisition. Therefore, it is desirable to operate a goniometer or a holder mechanically as less as possible. Meanwhile, advances in aberration correction technology have been remarkable and three-hexapole type STEM corrector, Large Aperture STEM Corrector (LASCOR), was recently developed by CEOS GmbH [1, 2]. It is capable of correcting aberrations up to sixth-order three-lobe aberration which had been a limiting factor in the ASCOR corrector. With the LASCOR, the Ronchigram flat area has now been extended to 80 mrad in semi-angle at an acceleration voltage of 200 kV. Thanks to this large flat area, one can align crystalline zone axis using only optical elements (beam tilt and projector shift) of a microscope without any mechanical operation. In this study, we demonstrate a high-resolution STEM image acquisition using this technique.

The procedure is described here how to acquire STEM images of a specimen with a misaligned crystalline zone axis by the proposed method. Firstly, a condenser lens aperture is inserted at the center of the optical axis, and the electron beam is tilted by the beam tilt coils in Fig. 1. This beam tilt appears as the shift of a condenser lens aperture and it can be aligned to the crystal zone axis. The beam is detilted to the center of the detector plane by the projector alignment coils. In this setup, high-resolution STEM images are acquired.

Fig. 2(a) shows an experimentally recorded Ronchigram image with dashed circles indicating the amount of beam tilts used. As the flat area is as large as approximately 80 mrad in semi-angle, the electron beam can be tilted with little influence of geometrical aberrations. Fig. 2(b) ~ (e) show high-resolution STEM images of Si[110] single crystal obtained under different beam tilt conditions corresponding to the dashed circles in Fig. 2(a). It is demonstrated that even for a specimen tilt of over 60 mrad, atomic resolution imaging is achieved by aligning the zone axis using only the optical elements. However, under the tilted conditions, STEM images were blurred in the direction of the tilts, which can also be confirmed in each FFT image. It is assumed that the blurring is due to the effects of the combination of chromatic aberration and beam tilt. Further improvement of image quality can be expected by the use of a monochrometer or a chromatic aberration corrector. Although a specimen tilt causes defocus at the edges of an image and image shrinkage in the direction of the tilt, they can be corrected by changing the defocus during the scan and by a simple image processing, respectively. The correction parameters can be directly calculated by the azimuthal and tilt angles of the beam. The technique introduced here will facilitate an automated acquisition of STEM images and is expected to have applications in the field of semiconductor where it is particularly important to acquire a large number of STEM images quickly.

Simultaneous Acquisition of 4D and EELS Data by Newly Developed Pixelated STEM Detector

Dr. Ryusuke Sagawa[1], Mr. Hiroki Hashiguchi[1], Mr. Akiho Nakamura[1], Ms. Shoko Shibagaki[1], Mr. Yutaka Kazama[1], Mr. Martin Huth[2], Mr. Yassine Imari[2], Mr. Valentin Kroner[2], Mr. Stefan Aschauer[2]
[1]JEOL Ltd., Akishima, Japan, [2]PNDetector GmbH, München, Germany

IM-04 (1), Lecture Theater 1, august 27, 2024, 10:30 - 12:30

In scanning transmission electron microscopy (STEM), efforts to obtain specimen information as much as possible have long been made and variety types of detectors have been developed. Pixelated STEM detector is one of these instruments for utilizing diffraction information that was otherwise partly lost in the conventional single-channel STEM detectors. Various types of applications have been introduced using the 4-dimensional (4D) dataset which include synthetic STEM image reconstruction, field map visualization and phase image reconstruction by ptychography, etc. [1,2]. Meanwhile, electron energy loss spectroscopy (EELS) is also an important and popular means of obtaining information on the composition and even on the chemical bonding inside a sample. Considering the type of necessary electron signal for both 4D-STEM and EELS, they should go well with each other in many cases: the former needs a part of transmitted electron beam and scattered or diffracted beams and the latter needs a part of transmitted beam which is complementary to the former [3]. Although simultaneous analysis using both instruments has been anticipated, making a center hole in the middle of a pixelated detector to let electron beam pass through into an EELS spectrometer was a manufacturing challenge. PNDetector is a company manufacturing high-speed pnCCD camera which can be operated at 7,500 frames per second for the 4D-STEM application. It recently manufactured a prototype pnCCD sensor with a center hole while keeping other specs the same, realizing the simultaneous acquisition of 4D and EELS data [4].

The prototype pnCCD camera was installed on a JEM-F200 (JEOL Ltd.) electron microscope with a cold field emission gun (Fig. 1). Below the camera, CEFID (CEOS GmbH) EELS spectrometer was mounted. Scan was triggered by an ELA (DECTRIS AG) camera mounted on the CEFID as a post-filter detector. Then the microscope scanning system and the pnCCD camera readout were synchronized to it. In EELS application, scanning dwell time of more than several tens of milliseconds is usually required for a sufficiently high SN ratio of an EELS mapping data. In order to synchronize this somewhat slow scanning speed with the high-speed pnCCD camera, a multiple readout signals of the pnCCD camera was accumulated at each scanning position.

Fig. 2 shows the simultaneously obtained 4D-STEM and EELS data from a semiconductor sample. Fig. 2(a) shows a diffraction pattern image obtained at a certain position on the sample. Since the sensor has a hole, there is a circular area at the center of the image where no electron signal was generated. Camera length of the microscope was set so as to let the transmitted electron beam pass through the hole while keeping the diffracted signals inside the field of view of the camera. Fig. 2(b)~(d) are synthesized STEM images from each diffracted disk in Fig. 2(a). Because all the diffracted disks were recorded at every scanning position, different image contrasts were obtained from the same field of view, thus, the 4D-STEM data acquisition was demonstrated. Fig. 2(e)~(h) show simultaneously obtained EELS elemental mapping images of oxygen, nickel, silicon and titanium, respectively. Each image has a sufficiently high SN ratio and one can clearly tell the locations of each element inside the sample.

Development of planar micro optics for ultrafast in-situ measurements in the TEM

Max Herzog[1,2], Dr. Johannes Schultz[1], Prof. Dr. Axel Lubk[1,3]
[1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany, [2]TUD Dresden University of Technology, Dresden, Germany, [3]Institute of Solid State and Materials Physics of TUD, Dresden, Germany

Poster Group 1

Background incl. aims
Efforts in the miniaturization of magnetic electron optics exist for at least 10 years now, because smaller electron optics not only require less material and are potentially easier to build, but also result in other favorable scaling effects. Firstly, the small pole distances allow for magnetic flux densities in the hundreds of millitesla with a significantly reduced energy consumption and lower overall complexity regarding vacuum and cooling. Secondly, the small size translates to a low inductivity, which in turn enables switching of the optics on short time scales/with high frequencies (HF). The aim of this work is to utilize those favorable scaling effects by building miniaturized, magnetic, planar micro optics that are capable of manipulating a fast electron beam like in TEMs on sub nanosecond timescales/with gigahertz frequencies, allowing for stroboscopic, time resolved measurements in that regime.
Methods
The micro optics are produced using lithographic structuring techniques. The first layer consists of the conducting copper paths with a thickness of several hundred nanometers. The second layer consists of sputtered permalloy with a thickness of 1 µm. Through this process, many different optics e.g. dipole deflectors, quadrupoles, and higher order multipoles with various pole geometries can be produced in an easily scalable way. In order to supply the optics, a custom TEM holder capable of transmitting HF signals was engineered. The holder carries a small circuit board on which the optics are mounted and that allows for impedance matching in close proximity. To characterize the electromagnetic fields, differential phase contrast (DPC) measurements were conducted. The HF capabilities of the dipole optics were characterized in diffraction mode by measuring the amplitude of the oscillation of the diffraction disc.
Results
The optics show deflections in the single to double digit µrad range at 300 kV acceleration voltage and no major drop off in deflection up to an AC excitation frequency of 2 GHz. This corresponds to a maximum magnetic flux density of 84 mT and a possible focal length of a quadrupole of 15 cm at an acceleration voltage of 80 kV.
Conclusion
Miniaturized planar electron optics can be produced such that their diffraction capabilities especially in the HF domain are powerful enough to make them interesting for novel applications like stroboscopic, time resolved measurements on sub nanosecond time scales, imaging phenomena like the motion of domain walls with time resolved TEM. Furthermore, the miniaturization of entire CPO instruments e.g. SEMs might become possible in the future.

IM-05 (2), Lecture Theater 3, august 26, 2024, 14:00 - 16:00

Background incl. aims
The exploration of insulator-to-metal transitions (IMTs) in Mott insulators and strongly correlated systems has revealed intriguing phenomena induced by various stimuli such as temperature, pressure, doping, or electric fields [1,2]. Despite significant advancements, the mechanisms governing electronic phase separation at the nanoscale remain elusive. Addressing this knowledge gap requires a comprehensive approach, considering structural and electronic degrees of freedom. In this context, our study aims to investigate the temperature-driven IMT in (V0.988Cr0.012)2O3 (see Figure a), employing advanced techniques capable of probing multiple features simultaneously. The Cr-doping enables us to explore transitions from the paramagnetic insulator (PI) phase to the paramagnetic metallic (PM) phase around 200 K and also from the PM phase to the antiferromagnetic insulator (AFI) phase below 180 K. Interestingly, the PI/PM transition is isostructural of the hexagonal structure (space group R-3c) while the PM/AFI transition is associated with a crystallographic symmetry breaking into a monoclinic structure (space group I2/a). There is, therefore, a strong interest in investigating both spectroscopically and structurally this material using the same in situ tool.
Methods
To achieve our objectives, we employ in situ monochromatized EELS [2] and 4DSTEM micro/nano-diffraction [3] techniques. These experiments are conducted using a state-of-the-art NION Ultra-HERMES 200 microscope, equipped with a Medipix direct detector and a HennyZ double tilt cryo-holder. This cutting-edge instrumentation allows us to unravel intricate details associated with the IMT process.
Results
Specifically, we focus on identifying variations in low-loss spectra, highlighting fingerprints of the PI, PM, and AFI phases (Figure b). By comparing structural information acquired by 4DSTEM with such spectroscopic signatures, we probe a phase coexistence at low temperatures, as depicted in Figure c [4].
Conclusion
Overall, our results highlight the instrumental capabilities of high-energy resolution EELS as a valuable tool for unraveling the intricate dynamics of IMTs, offering new perspectives on the underlying physics of these fascinating phenomena.

Depth Dependence of Electron Channeling Contrast Imaging in Gallium Nitride

Etienne Lavallee[1,2], Mr. Antoine Guitton[2], Mr. Peter Imrich[1], Ms. Claire Chisholm[1]
[1]KAI Kompetenzzentrum Automobil-und Industrieelektronik GmbH, 9524 Villach, Austria, [2]Université de Lorraine, CNRS, Arts et Métiers, LEM3, Metz, France

Poster Group 2

Background incl. aims
Interest for Gallium Nitride (GaN) and wide band-gap semiconductors has been growing the last few decades as a green-energy solution for electronic power devices and digital transition. Their enhanced electrical properties such as reduction of power losses or lower energy consumption tends to make them more suitable for power electronics applications over silicon. However, it is unclear whether leakage currents or device failures are related to crystalline defects, such as Threading Dislocations (TD), for which defect densities in GaN are orders of magnitude higher than in silicon. Detailed characterization of the defect nature and estimation of their density is, therefore, relevant to understand and improve GaN power devices. In this context, Electron Channeling Contrast Imaging (ECCI) can provide valuable insights. ECCI is a non-destructive method that offers the capability to provide Transmission Electron Microscopy (TEM)-like diffraction contrast imaging inside a Scanning Electron Microscope (SEM) on bulk samples. ECC is generated from electrons that channel down the crystal planes. Strain and defects cause distortion of the crystal lattice, resulting in changes in Backscattered Electron (BSE) intensity, thereby producing contrast in the image.
Diffraction contrast in bulk material is widely assumed to be generated from the near-surface layers (from tens to hundreds of nanometers) by electron channeling but there is currently no consensus about the depth from which the collected information originates. Therefore, it is critical to understand the depth dependence of the method to ensure measurements are made in the layer of interest.
The present study provides an experimental measurement of the signal from which the information in ECCI arises. This estimation aims to sharpen the statistical dislocation density estimation through series of measurements at different accelerating voltage and to establish a model for information emission while imaging GaN by ECCI.

Methods
The layer of interest, the GaN layer, lies between an AlxGa1-xN barrier layer and a series of strain-relief layers called the superlattice, for which the composition differs from the first one. As such, misfit dislocations, due to lattice mismatch, stand at the interface between the GaN and the superlattice. A Focused Ion Beam (FIB) was used to create wedges of different angles across these layers to vary the GaN layer thickness. The incident electron beam energy of the SEM was varied and the final depth the misfit dislocations were visible was recorded. Comparisons between multi-beam and 2-beam diffraction conditions was also performed.

Results
First results show ECCI probing depth can be tuned as a function of incident electron beam energy and that there are discrepancies between multi-beam and 2-beam diffraction conditions as well as the theorized channeling extinction distance and the experimentally measured probing range.

Conclusion
The key expected outcomes are an increase in estimated dislocation density accuracy in GaN and a better understanding of ECCI micrographs. The dataset is expected useful for complementary dislocation related fields of study such as layer growth or electrical characterization.

2 Curtin Institute of Functional Molecules and Interfaces School of Molecular and Life Sciences, Curtin University GPO Box U1987, Perth, WA 6845, Australia.

Background:
The use of nanomaterials in catalysis has consistently sparked significant scientific interest, primarily due to their high surface-to-volume ratio and the ability to finely control active sites. This study focuses on exploring the characteristics of Cu3P engineered in the shape of nanocages, with promise as a catalyst for CO2 reduction[1]. To achieve a comprehensive understanding of the system, we combined the 3D morphology obtained via electron tomography with compositional data from energy-dispersive X-ray spectroscopy (EDX), and local chemical states estimates from electron energy loss spectroscopy (EELS). The resulting understanding of the Cu3P nanocages will lead to optimal design of the structures and improvement of the catalytic performance.
Methods:
In our investigation of Cu3P nanocages, we utilised a probe-corrected ThermoFisher Spectra 300 transmission electron microscope (TEM) to define their morphological, structural, and elemental characteristics at high spatial resolution. We acquired several tilt series over a tilt range of at least 120° over isolated and assembled nanoparticles. STEM-EDX data were acquired using a Dual-X detector (collection angle ~1.7 sr), while EELS data were acquired in a Continuum GIF. Additionally, for a comprehensive examination of this nanosystem, we conducted an extensive compositional study by integrating machine learning algorithms[2] with hyperspectral EDX and EELS datasets.
Results:
Through the synergistic application of these different techniques, we gained a comprehensive understanding of structural and electronic properties of Cu3P nanocages, with an average size of 15 nm. Multivariate analysis played a crucial role in discerning compositional variations within these nanostructures. In particular, principal component analysis (PCA) and non-negative matrix factorisation (NMF) were employed on both compositional datasets (EDX and EELS core loss), allowing a deep understanding of the elemental distribution within the nanocages. This approach allowed us to uncover subtle differences in the elemental distribution of nanocages, shedding light on the intricate interplay between morphology, structure and elemental composition in these catalytic nanostructures. The analysis of the fine structure of EELS edges also enables the differentiation between oxidation states for copper through the structure. Such multidimensional analysis not only improves our understanding of Cu3P nanocages, but also shows the power of integrating microscopy techniques and advanced data analysis methods that enable comprehensive characterisation of nanomaterials. In addition, by combining electron tomography information with

compositional information, we were able to visualise the three-dimensional morphology of nanocages, providing fundamental information about the nature of these catalysts.

Conclusion:
This research contributes to the advancement of nanocatalysis and underscores the paramount importance of microscopic investigations in comprehending and refining catalytic processes. The combination of various techniques, such as EELS, EDX, and electron tomography within a TEM, presents a complete approach to studying nanocatalysts like Cu3P nanocages for CO2 reduction. These methodologies enable an in-depth examination of the structural characteristics, elemental composition, and three-dimensional morphology of catalysts. Concurrently, this study serves as a demonstration of the role played by machine learning algorithms in processing microscopy data. The synergy between machine learning and the advanced capabilities of next-generation microscopes introduces novel avenues for researchers to efficiently optimise and refine the interpretation of generated data, thereby unlocking the full potential of advanced microscopy technologies.

Poster Group 1

The flatness of laser-based illumination and the available power have a major impact on image quality and can restrict the contrast and precision of many techniques, including the localisation precision of single-molecule localization microscopy (SMLM). In addition, different laser sets usually need to be provided for different microscope methods, leading to complicating the development of multimodal devices.

The Universal Laser Engine combines:
* a flat top-hat illumination, even within the µs-range
* a set of high-speed switching lasers
* picosecond pulsed lasers for fluorescence lifetime applications.

We have proven the applicability of the Universal Laser Engine for wide-field, confocal and TIRF microscopy. It allows to combine multiple methods for simultaneous measurements, such as alternating multi-color excitation schemes, super-resolution and lifetime approaches. Based upon the Universal Laser Engine and zero-mode-waveguides, we parallelised single-molecule and detection and implemented a 12-spot parallel FCS detection. Together with the LINCam, we achieved simultaneous STORM & wide-field FLIM recordings.

IM-05 (3), Lecture Theater 3, august 27, 2024, 10:30 - 12:30

Background incl. aims:

Bimetallic nanoparticles (BNPs) have attracted increasing attention in fundamental and applied sciences in recent decades. They are expected to play a central role in the energetic and ecological transition of our societies. Combining two or more metals on the nanoscale opens up a whole playground for the investigation and the fine-tuning of physicochemical properties and applications in nanoparticle-based devices. The BNP properties depend on size, shape, environment, chemical composition and spatial elemental distribution. Different chemical configurations (alloyed vs. segregated, chemically ordered, etc.) can change considerably the optical, magnetic, or catalytic properties via the electronic structure [1]. One of the most intensely studied bimetallic systems is the gold-silver alloy. Its nanoparticles have attracted much attention for their catalytic, plasmonic surface-enhanced sensing and photocatalytic properties. In the bulk, the two metals are completely miscible across the entire composition range, and their atomic radii, crystal structure, valence, and electronegativity are very similar. On the nanoscale, however, additional degrees of freedom have to be considered, namely the particle surface, as well as possible segregation and chemical ordering into structures not possible in bulk. Despite the high number of experimental and theoretical articles published on AgAu nanoparticles, the controversy about whether intrinsically one of the two metals preferentially segregates at the surface or not is still unresolved, both on the experimental as on the theoretical side [2,3]. In this context, we aim to contribute to this discussion by providing quantitative and statistically reliable chemical profiles of AgAu BNPs in the chemical ground state and thermodynamic equilibrium, using high signal-to-noise ratio and resolution hyperspectral images (HSI) obtained by Energy Dispersive X-ray Spectroscopy (EDS).

Methods:

The performance of EDS combined with Scanning Transmission Electron Microscope (STEM) has been significantly enhanced, permitting the analysis of chemical composition in nanometric objects, including bimetallic nanoparticles (BNPs) with diameters smaller than 10 nm. This breakthrough is crucial for the in-depth distinction between different chemical structures (random, gradient, or core-shell, etc.) of individual particles on a quantitative level. High-quality SNR are difficult to attain for such very small volumes, below 10 nm; besides, data acquisition and treatment methodologies, followed by rigorous error analysis, are essential. In this context, we have measured the chemical composition variations inside AgAu BNPs using EDS-STEM in a Titan-Themis Cubed and a Cold-FEG JEOL NeoARM operated at 80 kV with high solid angle X-ray detectors (≈1 sr). We have used unsupervised machine learning methods (Principal Component Analysis-PCA and Nonnegative Matrix

Factorization-NMF) to verify the existence of latent information on radial composition variations in our data. This analysis provides direct, solid statistical verification that the estimated radial composition changes represent accurate information provided by the EDS spectra [4,5]. In addition, PCA and NMF components are used for the reconstruction of the dataset for denoising and background removal, respectively.

Results:

To guarantee that the BNPs are analyzed in the chemical ground state, we protect them by a thin layer of amorphous carbon and anneal them at 300°C. Analyzing the HSIs using PCA and NMF, we are able to retrieve denoised information for quantitative analysis, but we can also evidence the Ag segregation of hundreds of BNPs by analyzing the components and abundance maps obtained by PCA/NMF, both showing compelling complementarity to EDS-HSI datasets. Using unsupervised machine learning to provide statistical validation for the information extraction, we further analyze quantitative profiles by azimuthal averaging (to attain better SNR) of isotropic BNPs in the HSI for both raw and NMF reconstructed data. Here, our results demonstrate the possibility of quantifying the chemical composition within bimetallic nanoparticles in 4-10 nm in diameter range. These findings represent a significant improvement over the widely used qualitative chemical mapping (see Fig 1.), providing essential insights into understanding the elemental distribution within small volumes. Our results reveal chemical gradients with Ag enrichment towards the surface of the BNPs.

Conclusion:

Finally, by combining well-defined model samples, robust and quantitative EDS-TEM analysis and machine learning for statistical validation we contribute to the comprehension of nanoalloy physics. We not only demonstrate the feasibility of the method but settle the ongoing controversy about nanoscale miscibility in the AgAu system. While Au and Ag are miscible in in the core of BNPs as small as 4 nm in diameter, with a core of 2 nm (<400 atoms), a slight enrichment of silver at the surface of the order of 10% is consistently evidenced. Our work furthermore paves the way for its extension to environmental and tomographic studies of multimetallic nanostructures.

Background
The catalytic and optical properties of bimetallic gold-palladium (Au-Pd) nanoparticles (NPs) critically depend on the atomic distribution of the Au and Pd atoms [1]. Under operating conditions, the atomic distribution is highly dynamic. Analyzing gas induced redistribution kinetics at operating temperatures is key in understanding the behavior of Au-Pd nanoparticles but requires advanced in situ characterization strategies. In situ transmission electron microscopy (TEM) allows direct visualization of changes in metal nanoparticles at elevated temperatures and/or upon exposure to reactive gases. So far, several TEM studies on alloying dynamics of core-shell nanoparticles under high vacuum have been reported using EDX (energy-dispersive X-ray) mapping, fast tomography, and atomic resolution imaging [2]. However, these methods are difficult to utilize in the presence of a gas atmosphere because 1) EDX is time consuming and requires a high electron dose rate, which can lead to undesired beam effects, 2) the fast tomography approach is not possible with the current in situ TEM holder technologies, which do not allow tilting at the needed range, and 3) high resolution studies are often limited to only one nanoparticle. Assessing the effect of a gas atmosphere on the alloying dynamics of NPs has therefore remained unexplored and requires new methodologies for extracting the alloying kinetics from in situ gas-phase TEM data.
In this work, we use in situ gas-phase TEM to directly observe the effect of a reducing or oxidizing gas atmosphere on the surface and bulk alloying kinetics of Au-Pd nanoparticles [3]. We developed a methodology to quantify the alloying dynamics of core-shell NPs from high angular annular dark field scanning transmission electron microscopy (HAADF-STEM) images acquired at atmospheric pressure without the need of EDX, fast tomography or atomic resolution imaging, imaging around 35 nanoparticles per gas atmosphere. Using this approach, we assess the NP bulk alloying dynamics from the in situ TEM data and show that the observed alloying dynamics can be predicted using a simple diffusion model based on Fick's second law.

Materials and Methods
The in situ gas-phase HAADF-STEM measurements were performed using a Protochips Atmosphere system and a Talos F200x microscope operated at 200 kV. Prior to beam exposure, the sample was heated to 250 °C in 5% H_2 in Ar for 45 minutes to ensure the removal of water and reduction of oxidized species. During the experiment, the gases (H_2 or O_2, 10% diluted in Ar) were introduced at 1 bar and 0.1 sccm flow rate. The sample was heated to 375 °C for a total amount of time of 1 h, being paused at 18 time points to perform imaging at room temperature. The impact of the temperature on the alloying kinetics was assessed by conducting an additional experiment at 350 °C. The temperature ramp was 10 °C/s and the beam was always blanked at high temperatures. The data were analyzed using custom made python scripts quantifying the intensity decrease of the Pd-shell related grey values over time, thereby indicating progress in the alloying. After the experiment, the Au-Pd NPs were analyzed using EDX mapping in vacuum.

Results and Discussion

The alloying kinetics of the Au-core Pd-shell NPs were monitored through in situ TEM in oxidizing and reducing gas atmosphere. HAADF-STEM images of around 20-25 core-shell Au-Pd NPs (23.8 ± 1.3 nm diameter, 36 ± 5 atomic % Pd) were taken in the course of 1 h exposure at 375 °C under a H_2 or O_2 atmosphere. At time = 0 min, the core-shell structure with the light grey Pd-shell and white Au-core is visible due to the different Z-contrast of Au and Pd, which is lost upon alloying (Figure 1a,b). By monitoring the intensity decrease of the grey values related to the Pd-shell (Figure 1c) and normalizing it over all NPs, we obtain an indication of the kinetics of the alloying process of the whole NP. To validate this approach, we performed an in situ heating experiment under vacuum to be able to follow the alloying process both by EDX and HAADF-STEM imaging. This confirmed that our HAADF-STEM based data analysis correctly quantified the alloying process.

We find that the temperature impacts the alloying kinetics more strongly than a change in gas atmosphere. We verified that the electron beam did not affect the alloying kinetics by imaging 10-15 NPs less frequently, and by performing EDX mapping of irradiated and non-irradiated areas after the experiment. The temperature dependence of the alloying process can be described by a simple model based on Fick's second law. The modeled diffusion behavior at 350 and 375 °C shows good agreement with datapoints derived from the in situ TEM data (Figure 1d). This validates our in situ TEM approach, and it also shows that the modeled diffusion behavior is accurate for nanoparticle systems.

Conclusions

In this work, we quantified the alloying dynamics of bimetallic nanoparticles with in situ gas-phase TEM for the first time. To do so, we followed the loss of the core-shell structure of ~35 Au-Pd core-shell nanoparticles using their difference in Z-contrast in the HAADF-STEM images. The alloying kinetics were highly impacted by a change of temperature and to a lower extend by the gas atmosphere. Quantitative insight such restructuring phenomena at elevated temperatures and in catalytically relevant gasses is critical in understanding changes in the behavior of nanoparticle catalysts under operating conditions.

Cryogenic scanning electron microscopy of hereditary hemolytic anemias

Irina Davidovich[1], Mrs. Carina Levin[2,3], Mr. Yeshayahu Talmon[1]
[1]Department of Chemical Engineering and the Russell Berrie Nanotechnology Institute (RBNI), Technion-Israel Institute of Technology, Haifa, Israel, [2]Pediatric Hematology Unit, Emek Medical Center , Afula, Israel, [3]Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel

Poster Group 1

Background:
Hereditary hemolytic anemias are a heterogeneous group of genetic disorders, in which red blood cells (RBCs) are removed from the bloodstream faster than they are produced. The main hereditary conditions include RBC membrane disorders, RBC enzymatic defects, and hemoglobinopathies, such as sickle-cell disease (SCD) and β-thalassemia. Different disorders may overlap, resulting in a wide range of clinical symptoms. Imaging techniques, especially light microscopy (LM), are essential for diagnosis of hemolytic anemias. However, many essential processes such as the exact mechanism of RBC sickling are not fully understood yet. The indication of the unique structural properties of different types of cells and the evolution of their morphological changes upon specific conditions requires high-resolution methods.
Cryogenic scanning electron microscopy (cryo-SEM) combined with high-pressure freezing (HPF) specimen preparation can bring new useful information to hematological research. It allows examination of cell morphology and ultrastructure, interactions between blood components, and cell dynamics with nanometric resolution, close to their native state. Cryo-SEM is still rarely used for the evaluation of blood cells, and the aim of the work was to demonstrate the potential of this technique for hematological research.
Methods:
Whole blood samples from the patients with β-thalassemia major, homozygous and heterozygous cases of SCD, and with glutamate-cysteine ligase (GCL) deficiency and β-thalassemia trait coinheritance, were evaluated and compared with a healthy control, S trait person, GCL deficiency heterozygote, and a β-thalassemia carrier controls. The SCD blood samples were incubated with sodium metabisulfite to provide low-oxygen conditions and induce morphological changes. These samples were examined using LM, flow cytometry, and cryo-SEM at different stages of sickling. Cryo-SEM samples were prepared by high-pressure freezing (HPF). The uncoated cryo-specimens were imaged by a Zeiss Ultra Plus cryo-SEM, equipped with a field emission gun, at low beam acceleration voltage (1.2 kV). No cryoprotectants or stains were used.
Results:
Cryo-SEM reveals abnormal morphology in most RBCs from the patients. Blood specimen from a patient with β-thalassemia demonstrates evidence of cytoskeleton rupture with indicative membranal damage. Fig. B demonstrates the shell-like RBC morphology that was the most common in this patient. We followed the changes of erythrocyte morphology in the SCD patients due to the hypoxia condition, when focusing on different stages of the sickling process. Fig. C shows the typical sickled RBC characteristic of SCD patients after exposure to low-oxygen conditions. In the patient with GLC deficiency and β-Thalassemia Trait Coinheritance, we found a variety of RBC morphologies and signs of membranal damage including membranal blebbing and almost complete cell disintegration (Fig. D). These abnormalities are not seen in RBCs from carriers and healthy individuals (Fig. A).

Conclusions:
This work presents the first study of RBC morphology and ultrastructure in patients with hereditary hemolytic anemia using the novel cryo-SEM methodology. The micrographs reveal details of the erythrocytes that cannot be seen using conventional methods. We found membrane and morphological abnormalities, probably caused by oxidative damage, which is a key component of the hemolytic process in these diseases. We also proposed the mechanism for the RBC sickling process in SCD patients. This study highlights the potential of the cryo-SEM methodology for a deeper understanding of hematological disorders.

IM-10 (3), Lecture Theater 5, august 30, 2024, 14:00 - 16:00

Background:
In catalysis research, the amount of microscopy data acquired when imaging dynamic processes is typically too vast for non-automated analysis. Consistent image segmentation is a common first step to obtain data that can be correlated with time-dependent chemical observable. Developing machine learned segmentation models is challenged by the requirement of more high-quality annotated training data than is available in most cases. In our approach, we thus substitute expert-annotated data with a physics-based sequential synthetic data model.
We study environmental SEM (ESEM) data collected from the process of propanol oxidation to acetone over cobalt oxide. After raising the temperature to 350 °C during the reaction a phase transition occurs, reducing the selectivity of the catalyst towards acetone. This phase transition manifests in the µm-scale ESEM data as the formation of cracks between the pores of the catalyst surface. The aim is to generate synthetic data to train a neural network capable of performing semantic segmentation (pixel-wise labelling) of this ESEM data. Statistical analysis of this data will lead to greater insights into this phase transition.

Method:
To generate synthetic image data that approximates the observed transition, our algorithm composes ESEM images of the pristine room-temperature catalyst with dynamically evolving synthetic cracks satisfying two physical construction principles, gathered from empirical knowledge about the phase transition. First, crack growth propagates along surface paths which avoid close vicinity to nearby pores in the surface. Second, each growing path successively widens and is rendered with increasing contrast over short sequences of frames, allowing the algorithm to mimic the growth of the crack features on the surface. The synthetic dataset generated using this algorithm is then used to train a U-NET-LSTM recurrent convolutional neural network. This network architecture consists of a U-NET component with a convolutional Long Short-Term Memory cell appended.
Results:
To evaluate the quality of the neural network, and by extension the synthetic data generation algorithm, two neural networks were trained. The physics-based network was trained on a synthetic dataset generated as described above, and the random network was trained on a similar synthetic dataset, with the restriction that the crack growth paths avoid close vicinity to pores removed. These models were then benchmarked against each other using a synthetic test set to evaluate the importance of this physics-based component of the synthetic dataset. The results show that the physics-based network has a much lower rate of false positives than the random network, at a cost of a slightly lower rate of true positives. This is reflected in the resulting Dice-coefficients of 0.76 (physics-based) and 0.64 (random).

The physics-based network was then applied to the original ESEM movie, giving a fully semantically segmented dataset as the result. From this, statistics about the evolution of crack features could be extracted. Their analysis revealed that the crack feature is first visible to the ESEM about 100 minutes after the acetone selectivity loss event.
Conclusions:
By integrating physical characteristics of the features on the catalyst surface into a synthetic training data generation algorithm, we obtained a network with superior accuracy and a greatly decreased false positive rate. By taking advantage of the temporal nature of the data through the use of a recurrent Long Short-Term Memory layer, we improved the confidence and accuracy of the model further.

Poster Group 2

Electrochemical liquid-phase electron microscopy (ec-LPEM) has been successfully applied to understand catalyst degradation during CO2 electroreduction (CO2ER).[1] However, to be able to fully reproduce full cell conditions at these highly cathodic potentials, further advances in imaging and electrode configuration are required. Herein, we have integrated tri-layer graphene to serve as a liquid-sealing membrane and a substrate electrode material and tested its applicability for studying nanocatalysts at realistic CO2ER potentials.[2]
All experiments were carried out in a dedicated scanning electron microscopy (SEM) stage that is equipped with bulk reference and counter electrodes. The fabrication of the working electrode started by patterning a single Pt electrical pad on a Si/SiNx electrochemical chip with an electron transparent window. Holes were perforated onto the 50 nm thick SiNx membrane in a cleanroom. Tri-layer graphene was obtained via PMMA-assisted wet transfer of monolayer graphene sheets. The final tri-layer graphene was wet transferred on the electrochemical chip, ensuring the coverage of the electrical contact and membrane area. To assemble the graphene electrochemical microcell, the graphene chips were treated with H2 plasma to ensure their hydrophilicity. Subsequently, Cu nanocubes (NCs) were drop-casted on the graphene region overlapping with the perforated SiNx support membrane.
First, we evaluated the inert potential range and stability of the graphene cells and the results showed that the graphene electrode has a wider inert potential range in the cathodic region than the conventionally used glassy carbon electrode. Graphene was also found to have a stable current profile for up to 10 min at a cathodic potential of -1.1 V vs RHE, which is common for bulk cell CO2ER studies. In addition, cyclic voltammetry tests with Cu2O NCs loaded on graphene allowed for the investigation of Cu oxide reduction and oxidation peaks, confirming a good charge transfer between graphene and catalyst. Overall, the bench-top experiments demonstrate the suitability of graphene as a substrate electrode for CO2ER studies. Furthermore, in situ SEM control experiments showed improved spatial resolution with the graphene membrane and also demonstrated reduced electron beam induced damage in the bare graphene region compared to the SiNx region. However, in situ SEM electrochemical tests indicated the presence of adverse synergistic effects of e-beam and applied cathodic potential on the electrochemical stability time window of graphene electrodes. These effects are shown to be mitigated by minimizing the electron beam dose (i.e. probe current) or avoiding high cathodic potentials. Optimized in situ SEM experiments on Cu NCs, performed at -1.1 V vs RHE, a probe current of 16 pA and a duration of 3 min, revealed that their degradation proceeds via a subtle dissolution and redeposition mechanism during CO2ER.
In conclusion, this work demonstrates that graphene can play the dual role of membrane and electrode for investigating the degradation mechanisms of CO2ER catalysts under realistic potentials, while increasing the spatial resolution for ec-LPEM studies.

Poster Group 1

The colloidal bottom-up approach of nanoparticles self-assembling into ordered structures with tailored properties has recently attracted significant interest in various scientific fields. Therefore, their comprehensive structural and morphological characterization is essential, as the properties of these nanostructures are strongly correlated with their three-dimensional (3D) arrangement. Electron tomography is a common technique used for such nanoparticle characterization [1,2]. However, external forces that can affect the structure, such as the capillary forces caused by the common vacuum environment inside the microscope, are often neglected, resulting in misconnections between the obtained structure and the properties of the assemblies. As these materials are intended to be used in dispersion, our goal is to analyze the 3D arrangement of the assemblies in their native liquid environment. This innovative approach will allow us to establish a connection between the structure and properties of the assemblies under real working conditions.

In this contribution, we compare 3D reconstructions obtained in dry and liquid environments. We focus on two types of self-assemblies: gold NPs encapsulated in a polymeric shell and CTAB-coated gold nanorod bilayers. A commercial K-kit (Bio MA-TEK) liquid cell and a modified version with an increased angular tilt range (Tomochip [3]) were used depending on the assembly size. For larger assemblies, as the encapsulated gold NPs it is necessary to use larger window gap cells. However, this results in a larger background signal and limited tilt angles. On the other hand, smaller assemblies, such as the nanorods bilayers studied in this work, that can fit into the Tomochips, can benefit from a larger tilt range and lower background signal due to their reduced window gap.

The challenges of liquid-phase electron tomography have been addressed. Firstly, we adapted a fast acquisition approach to minimize the time and, therefore, the beam exposure of the sample, reducing possible beam damage. Secondly, we performed an interative denoise and rigid registration methodology to overcome challenges including increased background signal, low signal-to-noise ratios (SNR) resulting from scattering effects, and lengthy acquisition times required for two-dimensional (2D) projection images. Finally, we incorporate a compressed shape sensing method during 3D reconstruction to mitigate missing wedge artifacts from the limited tilt range and improve the SNR in the tilt series [4].

A comparison between similar 3D investigations performed in the native liquid environment and in dry state revealed a general decrease in interparticle distances in the latter. This effect can be assigned to the compression effect of the capillary forces generated by the vacuum environment of the electron microscope during dry characterization. These observations emphasize the importance of conducting measurements under liquid-state conditions to accurately characterize NP self-assemblies and provide essential insights into the underlying physical and chemical mechanisms that govern these structures.

Background incl. aims
Lithium-sulfur batteries (LSB) have emerged as a promising candidate for future energy storage solutions, leveraging the abundance, cost efficiency, and low environmental footprint of sulfur as well as significant theoretical capacity. These batteries feature a sulfur-infiltrated, highly porous carbon cathode immersed in an organic liquid electrolyte and paired with a lithium-metal anode. Despite their potential, the broader application of Li-S batteries is hindered by challenges such as suboptimal sulfur/lithium sulfide mass loadings, diminished rate performance, and the depletion of active materials. This depletion primarily results from the formation of mobile polysulfides, which can irreversibly react at the lithium-metal anode. A central challenge is the insufficient understanding of the sulfur-to-lithium sulfide conversion process, critical to the battery's functionality. [1]
In recent years, small-angle neutron and X-ray scattering have become popular for investigating LSB. However, interpreting the scattering data is notoriously challenging heavily reliant on the selection and tuning of appropriate models, thus introducing the potential for user bias [2]. Conversely, electron microscopy offers model-free access to structural analysis and provides local chemical resolution. Nevertheless, challenges such as a small field of view, demanding sample preparation and sensitivity to air and beam exposure complicate the probing of such samples [3].
In this work, we leverage recent advances in cryo-vacuum transfer TEM holders to enable the structural and chemical analysis of highly sensitive cathode materials, such as lithium sulfide [3]. We integrate this local information with operando small-angle neutron scattering (SANS) experiments to model the evolution of the multiphase cathode structure during cycling. Utilizing the composition revealed by cryo-TEM, we interpret the operando SANS data using Plurigaussian Random Fields (PGRF) models — a stochastic approach that provides representative 3D structures spanning several hundred nanometers. Given the computational intensity of solving this inverse design problem through PGRF, we train a generative adversarial model to expedite the simulation process.
Method
A binder-free, sulfur-infiltrated carbon cathode was dried and grinded in a mortar after discharge. A lacey carbon grid was then dipped into the powder. Next, the sample was transferred under Argon atmosphere from the glovebox to the TEM using the MelBuild Double Tilt LN 2 Vacuum Transfer Holder. During measurement, the sample was cooled down to -165°C to reduce beam damage. The samples were investigated using a JEOL GrandARM (ETHZ) operated at 300kV and a JEOL JEM 2200FS at 200kV. EFTEM and EELS measurements were conducted on the 2200FS.
The SANS data were acquired at the D-22 beamline at the Institute Laue-Langevin (ILL) using a custom-built cell. The cell, housed in a PEEK body, featured aluminum current collectors serving both as electrical conductors and neutron transparent windows. It incorporated a copper foil current collector, a Li metal anode, a glassfiber separator, a carbon black cathode, and an additional aluminum current collector. The azimuthally averaged intensity curve was fitted using a PGRF model.
Results

The cryoTEM measurements confirm a two-phase discharge product: one crystalline and the other amorphous. Similar discharge products have previously been reported in in-situ TEM cells using ether-based Li2S6 catholytes [4]. EFTEM and EELS analyses of the discharge particles reveal that the crystalline phase consists of Li2S, while the amorphous phase comprises a lower-order polysulfide (LOPS). Both primary particles are smaller than 10 nm, with the LOPS being approximately half the size of the Li2S particles. For subsequent modeling, we selected Li2S2 as the LOPS, which has been identified as a byproduct in LSB.
Building on the two-phase discharge product, we chose a PGRF model to analyze the SANS data. PGRF models are ideally suited for generating a variety of hierarchical, three-phase structures. By using a deuterated solvent in our battery, we adjusted the electrolyte's contrast to match that of the carbon matrix in the cathode, effectively reducing the number of signal sources to three: carbon/catholyte, Li2S, and Li2S2. Given the computational intensity of calculating scattering curves based on PGRF, we trained a convolutional neural network to predict the scattering curve from the PGRF model's input parameters. This model predicts a normalized curve with a mean squared error below 10^-4 and achieves a computational speed increase of three orders of magnitude (20 s reduced to 2.5 s). This acceleration enables the use of computationally intensive fitting algorithms. We opted for a Bayesian Optimization approach, well-suited for navigating through convex parameter spaces like those of PGRF. The parameters derived from fitting the PGRF model provide insight into the structural evolution of the cathode during operation, supporting the hypothesized solution-mediated conversion mechanism [2]. This mechanism involves the disproportionation of Li2S2 and its subsequent direct electroreduction to Li2S.
Conclusion
This study highlights the synergy between cryoTEM and SANS in revealing the conversion mechanism of lithium-sulfur batteries (LSB), leveraging a cryo-vacuum transfer holder for detailed cathode analysis. By minimizing user biases and enhancing model selection accuracy, we've provided a clearer understanding of the cathode's structural evolution during operation. Our approach not only advances the field of energy storage by deepening insights into LSB conversion mechanisms but also sets a methodological standard for future research on conversion-type batteries

Powerful material characterization techniques excelling in terms of lateral resolution and sensitivity are needed to study nanoscopic materials and their transformation processes in 3 dimensions at the relevant spatial scales. State-of-the-art Focused Ion Beam (FIB) technologies allow not only to visualize nanoscopic 3D structures, but also analytical surface measurements with Secondary Ion Mass Spectrometry (SIMS). SIMS is a powerful surface analysis technique which uses energetic primary ions to sputter the surface of a sample and to generate secondary ions separated by a mass analyzer to record chemical information. Advantages of SIMS are the high sensitivity, the high dynamic range, the ability to differentiate between isotopes and the access to the complete periodic table. Typical SIMS analysis modes are mass spectrum recording, depth profiling, 2D, and 3D imaging. In the past, the correlation of high-resolution ion microscopy with in-situ SIMS has allowed to acquire complementary topographic and chemical information for a deeper understanding of samples in various domains, including material sciences, geology, and biology [1].
The IONMASTER magSIMS is a novel system devoted to correlative high-resolution 2D/3D imaging and SIMS nano-analysis. The system is a unique combination of a Liquid Metal Alloy Ion Source (LMAIS) [2] and a dedicated magnetic sector SIMS unit. Within the LMAIS various ion species are emitted simultaneously from a single ion source (GaBiLi [3] and AuGeSi sources available) and are separated in a downstream Wien filter within the FIB column. This allows to choose the most suitable primary ion species depending on the application and also to toggle within a few seconds between the ion species. This has for instance the advantage to use heavy (e.g., Bi+ or Au+) primary ions to delayer the sample stepwise and to use lighter primary ions (e.g., Li+ or Si2+) to image the sample at high spatial resolution. These image planes can be stacked and used to create a 3D volumetric reconstruction of the sample [4]. The SIMS unit is equipped with an insertable/retractable extraction optics to transfer the generated secondary ions through the magnet based mass analyzer onto a focal plane detector. The latter allows parallel acquisition of full mass spectra for each scanned pixel within the chosen field of view [5] which gives the user a multitude of possibilities to post-process and correlate the SIMS image data.
Further key strengths of this FIB-SIMS platform are the possibility to use application specific primary ion beams, i.e. the ability to switch quickly between reactive primary ion species to maximize either positive (e.g., Au+ or Bi+ single primary ions and clusters) or negative ionization (e.g., Li+ primary ions) of the sputtered particles. The small beam diameter of the lightest primary ions (Li+ and Si2+) allows to perform high spatial resolution imaging in SIMS (< 20 nm) . The low penetration depth of heavy Bi+ and Au+ (and clusters) primary ions into the material enables excellent depth resolution. Moreover, the combination of a LMAIS FIB, a Laser Interferometer Stage with CAD based navigation, and a magnetic-sector SIMS offers a high potential for automatized workflows.
In this contribution, we will present the key features and the working principle of the IONMASTER magSIMS system equipped with a LMAIS. We will show results on correlative 2D and 3D imaging focused on applications including CIGS solar cells (Figure 1), geological and microelectronics samples investigated on the recently developed nano-analysis system. Thus, we will demonstrate that the

new IONMASTER magSIMS paves the way for nano-analytics beyond the conventional methodology for sample analysis by combining the LMAIS technology with a stable stage and a SIMS unit for highest spatial resolution imaging.

Introduction:
Various biological systems can utilize guanine crystals in photonic structures. To synthesize structures of guanine that mimic these biological photonic systems, many factors of the crystallization need to be controlled, like the specific polymorphism, morphology, crystallographic lattice orientation, and the crystals' twinning. This requires new synthesis approaches, as well as novel characterization techniques. The possibility to acquire local crystallographic information by acquiring a whole diffraction pattern at each probed position in scanning transmission electron microscopy (STEM), a technique known as 4D-STEM, is thereby a promising technique to investigate twinning in more detail.
The aim of this study is to find synthesis approaches that can mimic guanine crystals utilized in biological photonic systems and link their properties to synthesis informed by their structure revealed by a combination of X-ray and state-of-the-art electron microscopy techniques.
Methods:
Guanine crystals were synthesized using a new synthesis approach using poly(diallyl di-methylammonium chloride) as an additive in solutions with pH levels of 13.
The resulting crystals were investigated with powder x-ray diffraction (PXRD), scanning electron microscopy (SEM), selected area electron diffraction (SAED), and 4D-STEM.
4D-STEM data was acquired at a low dose to avoid radiation damage to the guanine crystals. The resulting low signal-to-noise ratio made orientation mapping with commercially available programs challenging. Instead, the crystal orientation and lattice spacing changes were investigated with a center of mass (CoM) approach.
Results:
The synthesized guanine crystals adopted the same polymorph as those in biological photonic systems (β-guanine). They demonstrated flat and elongated structures, as also observed for crystals in biological photonic systems. Many crystals show kinks along their length, as exemplary pointed out by the arrow in the abstract figure. Via SAED, it was determined that these kinks coincided with twin boundaries in the crystals. Furthermore, diffuse scattering in the SAED pattern indicated disordered stacking of the guanine molecules. The novel CoM analysis of the 4D-STEM could relate the disordered stacking to smaller intergrown crystal domains. It indicated crystal growth by partly ordered granular nucleation. Such a growth of guanine was also observed in certain biological systems. From the CoM analysis, variations of the orientation and lattice spacing of the small crystal domains were mapped. Larger deviations from the averaged orientation and lattice spacing were found close to twinning boundaries, indicating strain minimization as the origin of twinning.
Conclusion:
The novel synthesis approach enabled tight synthesis control of guanine crystals with polymorph and morphology mimicking the polymorph and morphology found for crystals in biological photonic systems. The CoM analysis combined with an intricate understanding of the crystal structure and chemistry of guanine facilitated us to reveal otherwise inaccessible information about the crystal growth mechanism and origin of twinning in this, at first glance, seemingly simple yet biologically

extremely relevant system. The study demonstrates the strength of employing 4D-STEM, informed by crystallographic knowledge for studies of bio-inspired complex materials systems.

Poster Group 2

Background incl. aims
The demand for reducing the emissions of CO2 in the transportation industries has, as a direct consequence, increased the need for alloys with enhanced performances. For this purpose, enabling the combination of multiple hardening mechanisms via microstructural design is a key tool. In the present study, in addition to a high Hall-Petch hardening, a different “second phase” hardening of spinodal decomposition is introduced in nanostructured materials.
Methods
Binary systems with a miscibility gap are selected (Fe-Cr and Al-Ag) [1,2]. The nanograins were produce by Severe Plastic Deformation (SPD) using High Pression Torsion (HPT). The resulting nanostructures (characterized by TKD and ACOM-TEM [3]) were aged during different holding times, allowing to establish the kinetics of the spinodal decomposition. The latter was characterized by APT applying the Radial Distribution Function in order to determine the evolution of both the wavelength and amplitude of the 3D concentration fields [4]. Micromechanical testing including micro-bending was applied to evaluate the mechanical properties evolution.
Results
Nanograins were obtained for both studied alloys after 10 revolutions of HPT, with average grain size diameter of 51 nm for the Fe-Cr alloy and about 100 nm for the Al-Ag system repectively. After ageing for 100h at 525 °C, the Fe-Cr average grain size attained 159 nm, showing relatively stable grain size.
The Fe-Cr spinodal decomposition kinetics of the deformed samples were measured to be 10 times faster compared to the non-deformed state. As for the Al-Ag alloy, it presents a non-homogenous composition even in the quenched state (cryo set-up used).
The microhardness evolution of the Fe-Cr alloy after 100h ageing shows that the decrease expected due to the Hall-Petch effect is mostly compensated by the hardening due to the spinodal decomposition. However, the bending torsion values after ageing showed an embrittment of the material.
Conclusion
Binary alloys with nanosized grains were produced by SPD. The miscibility gap in the phases diagrams was exploited to produce spinodal decomposed systems. Therefore, alloy-design considering both hardening effects is proven to be possible. The spinodal decomposition showed to be faster in the deformed nanograin conditions. With the goal of obtaining harder and tougher alloys, optimizing the process parameter is required.

Proton exchange membrane fuel cells (PEMFCs) are electrochemical devices capable of generating electricity by oxidizing H2, reformate (H2 rich gas with carbon monoxide (CO) impurities) or other fuels. In recent times, metallic core-shell nanoparticles (NPs) (M@Pt, M=Ru, Rh…) have attracted a big interest as anode catalysts of reformate fed PEMFCs [1]. The high catalytic activity of Pt towards the HOR, together with the CO poisoning tolerance introduced by the accompanying metal make them ideal for heavy-duty applications. Furthermore, since in M@Pt NPs the less stable metal (Rh or Ru) is not directly exposed to the electrolyte, their stability is expected to be higher than in the corresponding alloyed NPs, which commonly suffer from dissolution and dealloying [2]. However, M@Pt can still suffer from degradation under fuel cell conditions by processes that are yet not fully understood, which hinders the design of more stable and durable catalysts.
We investigated the degradation behavior of Rh@Pt NPs by means of identical location-scanning transmission electron microscopy (IL-STEM). This quasi in-situ technique allows to overcome the limitations of the ex-situ techniques, in which only statistical general insights are possible, since in IL-STEM the changes of individual particles are tracked between potential cycles. In particular, we characterized the Rh@Pt NPs after 0, 1000, 4000 and 10000 potential cycles (0.06-0.8V, 0.1V/s). Furthermore, since many of the degradation phenomena take place in 3D (e.g., particle migration and corresponding aggregation), selected regions were reconstructed in 3D by means of electron tomography.
We observed particle migration on the carbon support in all the stages of the potential cycling. However, no widespread particle aggregation was observed, even after 10000 potential cycles. A slight Rh dissolution (up to 5 at.%) during the cycles was detected, which decreased as the number of cycles increased. Even though some small particles dissolved during the first 1000 cycles, the main degradation mechanism responsible for the loss of electrochemically active surface area was found to be particle detachment.
Our results indicate that the investigated Rh@Pt NPs present a remarkable stability, and show how IL-STEM can be used for studying the degradation of catalyst NPs.

Poster Group 1

Background
To enhance the chemical stability of a cathode active material (CAM) in a Li ion solid state battery (SSB) a protective coating is applied. Such a coating should have - in addition to the chemical stability - a high Li ion conductivity. LiNbO3 is one material having these properties, which is already successfully applied in SSBs [1,2]. Its ionic conductivity depends strongly on the structure, amorphous LiNbO3 has higher ionic conductivity than crystalline one. This leads to the need of detailed knowledge of the structure and the morphology of the material when applied as thin coating in a battery cell and the correlation of these properties with the electrochemical performance [1].

Methods
In this work we use three different LiNbO3 coatings calcinated at 80°C, 350°C and 550°C on LiNi0.6Co0.2Mn0.2O2 (NCM622) as CAM. To get insights on the structure of the coatings various scanning transmission electron microscopy techniques (STEM) like high angle and virtual annular dark-field imaging (HAADF & VADF), energy dispersive X-Ray spectroscopy (EDS), electron energy loss spectroscopy (EELS) and scanning precession electron diffraction (SPED) were used. To further elucidate the amorphous structure of the coating the reduced pair distribution function (rPDF) [3,4], which contains information about nearest neighbor distances in the material, is calculated from the SPED diffraction patterns. These structural results are then correlated to the electrochemical performance of a battery cell with the respective coated CAM.

Results
HAADF and EDS images show that for the samples calcinated at 350°C and 550°C the coating forms a homogeneous layer covering the entire NCM622 particles. In contrast to that the coating covers only a few parts of the NCM622 particle for the sample calcinated at 80°. SPED measurements show that in the case of 550°C calcination temperature the coating is crystalline whereas for lower calcination temperatures such as 350°C and 80°C the coating is amorphous. Further quantification of the structure of these two amorphous samples through the rPDFs reveals distinct differences in the inter atomic distances. These structural differences of the three samples also influence their electrochemical performance. The battery cell with the coated CAM calcinated at 350°C shows a higher capacity after around 300 cycles compared to the cell with the uncoated CAM. For the cells with the coated CAM calcinated at 550°C and 80°C the capacity during cycling is inferior to the cell with the uncoated CAM.

Conclusion
Correlations between structural results of LiNbO3 coating on NCM622 calcinated at different temperatures to the electrochemical performance of the material in a battery cell show that the best

performance is achieved by an amorphous coating covering the whole NCM622 particles. This is achieved at a calcination temperature at 350°C. Higher temperatures lead to a crystalline structure of the coating. Lower temperatures lead to a different amorphous structures as well as an only partial coverage of the coating. 550°C and 80°C calcination temperature of the coated CAM lead then to a poorer electrochemical performance of the battery cell.

Secondary envelopment of the human cytomegalovirus is a fast process, utilizing the endocytic compartment

Tim Bergner[1], Laura Cortez Rayas[2], Jens von Einem[2], Dr. Clarissa Read (Villinger)[1]
[1]Central Facility for Electron Microscopy, Ulm University, Ulm, Germany, [2]Institute of Virology, Ulm University Medical Center, Ulm, Germany

LS-06, Lecture Theater 4, august 30, 2024, 10:30 - 12:30

Background and aims: The human cytomegalovirus (HCMV), a member of the herpesvirus family, is an enveloped virus. It gains its final envelope by the critical but not well understood secondary envelopment process that takes place at the cytoplasmic viral assembly complex (cVAC). Partially tegumented capsids that were released from the nucleus and transported to the cVAC initiate a budding process into cellular membranes coated with viral glycoproteins. Previous studies present controversial results regarding the origin of the viral envelope, suggesting both, trans-Golgi and endosomal origin, as well as a similarity with exosomes (1-4). Thus, the identity of the membranes utilized for secondary envelopment remains unclear. This study investigated the role of endocytic membranes for secondary envelopment of HCMV.
Methods: Wheat germ agglutinin (WGA) either conjugated to a fluorophore or to horseradish peroxidase (HRP) were used for labelling of glycoproteins at the plasma membrane of HCMV infected cells. By this, endocytosed membrane could be visualized by fluorescence and electron microscopy (EM). Membrane marker screening was used to narrow down the potential origin of the membrane compartment used for cVAC formation and secondary envelopment. EM was used to directly visualize endocytosed membranes, HCMV capsids and their interactions. For EM, we adapted a WGA-HRP labeling protocol followed by the DAB reaction in living cells (5). Subsequently, EM samples were prepared by high-pressure freezing and freeze substitution for optimal membrane visibility and analyzed by quantitative transmission electron microscopy (TEM) and scanning transmission electron microscopy (STEM) tomography.
Results: WGA was taken up into different membrane compartments within the cVAC of HCMV infected cells, including early endosomes, multivesicular bodies, trans-Golgi and recycling endosomes. TEM analysis showed budding of capsids at WGA-positive membranes and numerous enveloped WGA-positive capsids at the cVAC. Almost 90% of all budding capsids and 50% of enveloped capsids were labelled with WGA within 90 min. This indicated a rapid turnover of membranes at the cVAC in which freshly endocytosed membranes were transported from the plasma membrane into the cVAC to be utilized by capsids for their envelopment and consequent release into the extracellular space. Furthermore, we could show that 30 min are sufficient to complete endocytosis from the plasma membrane and secondary envelopment at the cVAC. STEM tomography revealed budding of capsids at various membranes, including trans-sided Golgi cisternae.
Conclusion: The endocytic compartment serves as the major membrane source for the formation of the cVAC as an optimized environment for virion maturation and consequently, as the major membrane source for secondary envelopment of HCMV. Furthermore, we show that secondary envelopment of HCMV is a fast process, in which endocytosed membranes are transported from the plasma membrane to the cVAC within minutes to be utilized for envelopment.

An accessible Secondary Electron Hyperspectral Imaging approach to draw meaningful insights from scanning electron microscopy

James Nohl[1,2], Jingqiong Zhang[1], Lyudmila Mihaylova[1], Serena Cussen[3], Cornelia Rodenburg[1]
[1]Department of Materials Science and Engineering, The University of Sheffield, Mappin Street, Sheffield, UK, [2]The Faraday Institution, Quad One, Becquerel Avenue, Harwell Campus, Didcot, UK, [3]School of Chemistry, University College Dublin, Belfield, Dublin 4, Ireland

IM-05 (2), Lecture Theater 3, august 26, 2024, 14:00 - 16:00

Background
Hyperspectral imaging in the scanning electron microscope (SEM) commonly uses the energy dispersive X-ray (EDS/EDX) signal. The colour maps produced have become a staple part of analysis for visualising elemental heterogeneity and quantifying bulk elemental composition of hard materials. Now, automated collection and analysis routines have extended to secondary electron hyperspectral imaging (SEHI) and the ability to produce colour maps of surface chemical heterogeneity down to the nanoscale [1].
SEHI, combined with an accessible and automated data analysis tool, has yielded maps of surface chemical bonding, such as the surface functionalisation of soft materials, compounds of light elements, and crystallinity by cross-linking. As well as offering complimentary information to elemental composition, the emission characteristics of SEs offer improved surface sensitivity and spatial localisation versus X-ray imaging in SEM, particularly for softer materials.

Methods
In this implementation, SEHI data volumes are built by sequentially imaging with the through-lens-detector (TLD) with a mirror electrode which steps through a series applied voltage biases to act as a variable low-pass energy filter. Automated data collection routines control the cutoff energy of the low pass filter to acquire images quickly. Imaging is done at 1 kV accelerating voltage and < 50pA beam current to produce suitable signal to noise and SE yield close to 1, as well as to reduce SE2 background emissions, and to limit the beam dose received by the material.
The data volume is differentiated with respect to energy to plot local SE spectra and slices of energy ranges (Figure 1a) are summed to create maps which relate a colour to a chemical feature in the SE spectrum (Figure 1b-d).
The energy ranges for each colour channel can be identified without prior knowledge by a blind-source separation using a non-negative matrix factorisation (NNMF) method. The program for creating colour-SEHI images has been packaged and redistributed as a portable MATLAB application.

Results
The first demonstration of the colouring method is on a lithium metal anode used in lithium metal, lithium-sulphur and lithium-air batteries. The surface ‘platelets’ are heterogenous features in red which measure 250 nm across. Whereas lithium oxide morphologies were imaged over a 25 µm horizontal field width by windowless EDS. Ranking of surface chemical species by comparison to theoretical models was used to identify contributions from lithium hydroxide, nitride and carbon containing species and found the red regions to have a higher proportion of lithium nitrides and hydroxides while the blue range included more lithium-carbon compounds.

Applying the analysis to a spider dragline silk fibre reveals domains of nanoscale ordering due to cross-linking, which measure 45 nm across (coloured green, Figure1c). A higher proportion of cross-linking is indicated by more intense SE emissions at 1.1 eV denoting di-sulphide bridging.
At a length scale of 25 µm horizontal field width, the approach is applied to a perovskite solar cell material, which is a mix of organic methylammonium and inorganic lead iodide (ie. hard and soft) material. The automated approach to colouring identifies a two-phase material, to identify regions of lead iodide (PbI2) within an organic-inorganic perovskite.

Conclusions
This advance in SEHI analysis is an important extension of LV-SEM capability to map and identify regions of surface chemical bonding. This is achieved through an accessible data collection and analysis routine that applies hyperspectral imaging to the SE signal.
Characterisation of surface chemical bonding heterogeneity on bulk functional materials becomes accessible down to nanoscale even for soft matter, as demonstrated by mapping 45 nm wide cross-linked regions in spider silk where di-sulphide bridges are more prevalent. Light element compound distribution is identified on a lithium metal anode material as well as phase separation in an organic-inorganic perovskite solar cell material.
Having demonstrated the technique can be applied to characterise both organic and inorganic material, future studies will include the lithium metal anode post electrochemical cycling and growth of the solid-electrolyte interphase layer.

LS-04 (1), Lecture Theater 4, august 29, 2024, 10:30 - 12:30

Background incl. aims
Kidney transplantation is the treatment of choice for patients with chronic kidney failure. However, rejection of the transplanted organ is still common despite immunosuppression, with antibody-mediated rejection (AMR) providing the worst prognosis, and so improving the understanding of the mechanisms of rejection is central to developing alternative therapeutics with better patient outcomes. Current imaging methods mostly rely on 2D imaging of samples using either light or electron microscopy (EM) or extremely time-consuming 3D volume EM. In this study we wanted to utilise high throughput tomography (HiTT) to non-destructively image whole hydrated tissue biopsies in fixative using X-ray imaging[1]. With HiTT we use phase-contrast imaging, which is particularly good at imaging low X-ray absorbing material such as hydrated soft tissue. Each individual scan takes 2 minutes and 16 seconds to complete with 3D reconstructions complete in 30 seconds. The speed and quality of the images allows us to:
1. Screen and target areas of interest in the kidney biopsies for both confocal microscopy targeting specific immune cells and also serial-blockface SEM (SBF-SEM).
2. We aim to correlate all the information provided across different scales to both inform on potential changes happening in AMR but to also see if the ultrastructural information from the SBF-SEM can be correlated to differences seen at the tissue level in the confocal and HiTT imaging.
3. The final long-term aim is that these cross-correlations between the three different imaging modalities can be recognised using machine learning tools to help predict whether the kidney biopsies are showing signs of AMR.

Methods
Kidney tissue biopsies (1 mm diameter punch biopsies) taken from control and transplant rejection patients (AMR-high and AMR-low) are stored in fixative (1% para-formaldehyde (PFA)). These samples are then transported to Hamburg where they are imaged using HiTT. The biopsies are mounted in small pipette tips, still in PFA, and imaged at the P14 beamline on Petra III in Hamburg. The imaging process is repeated at four distances at an energy of 18 keV, using a 10x objective (to provide a pixel size of 650 nm), with a total exposure time of 72.4 seconds for each scan. The data are then automatically reconstructed and able to be viewed in 30 seconds. For the biopsies which are several mm long we perform a vertical stitch scan which enables the whole biopsy to be imaged. Following the non-destructive 3D imaging of the whole biopsy it is returned to the Francis Crick Institute in London, here the biopsy is sectioned and prepared for confocal imaging.
Following the confocal imaging of the vibratome slices they are processed for SBF-SEM. These heavy metal stained, resin embedded slices are then re-imaged using HiTT in Hamburg at 12.7 keV and using the 20x objective (325 nm pixel size). Each of the individual slices are imaged and reconstructed

in less than three minutes. The samples are then transported to EMBL Heidelberg where they are imaged using SBF-SEM. This will be targeted on regions of interest such as the glomeruli or peritubular capillaries using both the hydrated and resin embedded HiTT data. The HiTT, fluorescence and SBF-SEM data is correlated together in MoBIE² to allow investigation of different tissue features across multiple scales. This data is segmented with a combination of manual and semi-automated processes to help generate ground-truths for training machine learning models.

Results
Here we show that whole kidney tissue biopsies from the clinic can be imaged non-destructively in 3D, as shown in figure 1 it is already possible to observe differences between the control and AMR samples. From the X-ray data alone it is possible to identify and quantify the number of glomeruli and blood vessels present in the whole biopsy as well as observe features of disease such as inflammation. In combination with the correlated confocal data taken from the same biopsy it is possible to infer specific cell types between both modalities. This vibratome section was targeted as, based on the HiTT data it was known to contain glomeruli. This can then be registered to the SBF-SEM to show changes at the ultrastructural level on targeted structures located in the X-ray imaging.

Conclusion
The High-throughput X-ray imaging provided by HiTT has facilitated the 3D imaging of whole patient biopsies at a scale and in a time frame not seen previously. This data can then be correlated with both light and electron microscopy to reveal cross-scales changes occurring in AMR.

Background incl. aims
Self-organized nanoparticle networks (NPNs) poised at the percolation threshold are promising for bio-inspired information processing. These networks show non-linear responses, high dimensionality and avalanche dynamics similar to those observed in the brain. The objective of this study is the imaging of the current path through the NPN to study the distributed memristive switching events.
Methods
The neuromorphic NPN was fabricated in two steps. First, an insulating base-layer, consisting of Ag NPs with a CxOyHz shell, was deposited on pre-structured Pt electrodes on a Si chip with 1 µm thermal oxide. In a second deposition step, pure Ag NPs were deposited under continuous conductance monitoring until the percolation threshold was reached. The avalanche dynamics of the NPN with features of criticality were analyzed ex situ. Ultimately, this NPN was analyzed in the SEM (FEI Helios Nanolab 600 SEM/FIB with a field emission gun operated at 3 kV) with 2 complementary methods. First, during in operando biasing a changing active voltage contrast (AVC) was observed. Second, resistive contrast imaging (RCI) revealed directly the current path after biasing steps. For these experiments, Pt electrodes below the NPN were electrically connected in situ by micromanipulators with tungsten needles to an EBIC amplifier from Kleindiek company. To gain a better understanding of the current response of NPNs, we corroborate the experimental results with kinetic Monte-Carlo simulations.
Results
After biasing, RCI was used to observe directly the current path (see graphic) revealing changes in the connectivity after successive biasing steps, while the overall morphology of NP groups persisted. AVC revealed a step-like potential distribution (see graphic) that changed during static biasing. Simulations indicated that nano-gaps between NP groups lead to the step-like potential distribution that varies due to switching events.
Conclusion
Current path imaging using AVC and RCI indicates that the current path changes steadily during biasing due to the construction and deconstruction of memristive filaments in nano-gaps between NP groups. The changing position of the nano-gaps is highlighted by strong resistive contrast. Thus, we correlated the avalanche dynamics of the NPN with spatio-temporally distributed resistive switching events within the network with the complementary combination of AVC and RCI.

The technique of alloying FA+ with Cs+ is often used to promote structural stabilization of the desirable α-FAPbI3 phase in halide perovskite devices[1]–[3]. However, the precise mechanisms by which these alloying approaches improve the optoelectronic quality and enhance the stability have remained elusive. This work presents the investigation of the effect of cationic alloying in CsxFA1-xPbI3 perovskite thin-films and solar-cell devices. Selected-area electron diffraction patterns combined with microwave conductivity measurements reveal that fine Cs+ tuning (Cs0.15FA0.85PbI3) leads to a minimization of stacking faults (SFs) and an increase in the photoconductivity of the perovskite films (Figure 1). Ultra-sensitive external quantum efficiency, kelvin-probe force microscopy and photoluminescence quantum yield measurements demonstrate similar Urbach energy values, comparable surface potential fluctuations and marginal impact on radiative emission yields, irrespective of Cs content. Despite this, these nanoscopic defects appear to have a detrimental impact on inter-grains'/domains' carrier transport, as evidenced by conductive-atomic force microscopy, corroborated by drastically reduced solar cell performance. Importantly, encapsulated Cs0.15FA0.85PbI3 devices show robust operational stability retaining 85 % of the initial steady-state power conversion efficiency (PCE) for 1400 hours under continuous 1 sun illumination at 35 °C, in open-circuit conditions. These findings provide nuance to the famous defect tolerance of halide perovskites while providing solid evidence about the detrimental impact of these subtle structural imperfections on the long-term operational stability.

In the second study, utilizing a very low-dose electron beam, we observed local material loss taking place in a white striped contrast forming regularly along the SFs pathways (Figure 2a). We examined several hundreds of diffraction patterns in different leading FAPbI3-rich perovskite compositions and interestingly, the SFs domains in the cubic FAPbI3 phase were found to be predominantly oriented near the [011]C zone axis in all the perovskite films. This derived an implication that the (011) perovskite crystal planes seem to be structurally vulnerable for SFs formation and that can be a source of an intrinsic absorber instability. Based on these observations, an —asymmetric sulphur (S)— containing additive (the obtained material is named hereafter as target) was introduced into the empirically optimized Cs0.17FA0.83PbI3 perovskite precursor which manipulates the perovskite crystal growth and results in majorly oriented in-and out-of-plane (001) perovskite domains (Figure 2(b-g)). The target perovskite devices (with an active area of 0.2 cm2) were extremely stable, retaining > 93 % of their initial PCE for > 2100 hours at room temperature, and additionally, 1 cm2 active area target devices maintained T80 (the duration for the PCE to decay to 80 % of the initial value) for > 500 hours at 65 °C, all under continuous 1-sun illumination at the maximum power point tracking in ambient conditions. These findings demonstrate the critical role of eliminating SFs domains in realizing stable perovskite solar cell devices.

Figure 1. a-c) Bright-field TEM micrographs, d-f) The associated SAED patterns (The Cs content and zone axis are written on the top left and right side of the DPs, respectively), The yellow circles indicate the position of the selected-area for SAED pattern acquisition; and g) Histograms illustrating the impact of Cs content on the defect density. The estimated percentages are based on the number of diffracted domains (from all the obtained micrographs) featuring ⟦{111}⟧_C SFs or δ-CsPbI3 phases with respect to all the other different phases present in the samples.

Background incl. aims
Electron tomography (ET) is an indispensable tool for determining the three-dimensional (3D) structure of nanomaterials in (scanning) transmission electron microscopy ((S)TEM). ET enables 3D characterization of a variety of nanomaterials across different fields, including life sciences, chemistry, solid-state physics, and materials science down to atomic resolution. However, the acquisition of a conventional tilt series for ET is a time-consuming process and thus cannot capture fast transformations of materials in realistic conditions. Moreover, only a limited number of nanoparticles (NPs) can be investigated, hampering a general understanding of the average properties of the ensemble. Therefore, alternative characterization techniques that allow for high-resolution characterization of the surface structure without the need to acquire a full tilt series in ET are required which would enable a more time-efficient investigation with better statistical value. Here we propose surface-sensitive secondary electron (SE) imaging in STEM employed using a modification of electron beam-induced current (EBIC) setup as an alternative surpassing electron tomography.
Methods
SEEBIC and ET experiments were performed using an aberration-corrected Thermo Fisher Themis Z TEM operated at an acceleration voltage in a range of 60-200 kV. A custom-made transimpedance amplifier with a total gain of 2 GV/A and bandwidth of 8 kHz, electrically connected to the sample via a DENSsolutions Wildfire holder, was used to convert the SEEBIC signal into a voltage signal digitized by the Attollight OUDS II scan engine. No image filtering was applied during post-processing. ET data were acquired over a tilt range of ±72° with tilt increments of 3°. Reconstructions of the tilt series were performed using the SIRT algorithm implemented in ASTRA Toolbox 1.90 for MATLAB 2022b. Scanning electron microscopy (SEM) images were obtained using Thermo Fisher Helios Nanolab 650 with nominal spatial resolution down to 0.8 nm operated at an acceleration voltage of 5 kV.
Results
We have shown that both general morphology and side faceting of the NPs can be directly observed from SEEBIC images which is less obvious from conventional STEM micrographs. SEEBIC imaging enables a gain of up to 2 orders of magnitude in data collection efficiency in comparison to conventional ET while providing necessary topographical information. The superior spatial resolution compared to SEM was demonstrated. It was shown that even though SEEBIC requires to use of high primary electron beam currents, the optimization of experimental parameters allows for the reduction of the accumulated electron dose rendering SEEBIC equally or even more dose-efficient than ET. Finally, we describe the contrast artefacts arising in SEEBIC images and discuss their origin. Next, it was shown that direct access to surface morphology obtainable on the order of minutes opens up the possibility of using SEEBIC for high-throughput analysis of the helical morphology of chiral Au nanorods (NRs). The workflow to automatically quantify the helical morphology based on

SEEBIC images and a dedicated image quantification procedure was developed and used to calculate the helicity function of the NP ensembles. We have shown that this approach overcomes the limitation of poor statistics obtained by ET, which is limited to analyzing only a few particles per sample batch. Helicity function analysis revealed a significant polydispersity at the level of surface features. We found that the average helicity values, calculated for hundreds of NRs per sample batch were in good agreement with the optical properties of the sample, confirming that helicity measurements enable linking the nanoscale morphology with the chiroptical handedness.
Conclusion
We have demonstrated that SEEBIC can be considered an attractive approach for the characterization of NP morphologies with shorter acquisition and processing times in comparison to ET and superior resolution in comparison to SEM. It was shown that the helical morphology of chiral Au NRs, with significant polydispersity at the level of surface features can be efficiently quantified using high-throughput SEEBIC measurements.

Poster Group 2

Full-area passivating contacts solar cells based on SiOx/poly-Si stacks represent the key elements for the fast growing new generation of industrial silicon solar cells substituting the passivated emitter and rear cell (PERC) technology. The utilization of n-type wafers with an n-type contact at the back and a p-type diffused boron emitter has become the industry standard in 2024.
In this work, variations of this technology are explored, considering p-type passivating contacts formed via a rapid thermal processing (RTP) step on p-type wafers, which could be useful in conjunction with n-type contacts for realizing solar cells with passivating contacts on both sides. Here, a particular focus is set on investigating the influence of the applied thermal treatment on the interfacial oxide layer. Thin SiOx layers formed via UV-O_3 exposure of the wafer are compared with layers obtained through a plasma treatment with nitrous oxide (N_2O). The different steps for sample fabrication are depicted in Figure 1(a).
For both oxide types, the influence of the RTP thermal budget on passivation quality and contact resistivity is investigated, as presented in Figure 1(b). The N_2O oxide exhibits an excellent passivation quality (i.e. high implied open circuit voltage iVoc) in the range of high thermal budget, whereas the UV-O_3 oxide shows a pronounced degradation under these conditions. Simultaneously, the contact resistivity achieved with the N_2O oxide layer is comparable to that yielded by the UV-O_3 oxide. Prior research emphasised the importance of employing a higher thermal budget for contacts formed by RTP to ensure both sufficient lateral conductivity of the poly-Si layers and compatibility with localized metal contacts [1]. These results demonstrate that fabrication of the thin SiOx by N_2O oxidation can be a viable solution to obtain high passivation quality in the high thermal budget range.
To unravel the mechanisms behind the improved performance obtained with the N_2O oxide at high thermal budget, high resolution TEM is conducted on layer stacks featuring both N_2O and UV-O_3 oxides after RTP at T=860°C, as presented in Figure 2. A break-up of the UV-O_3 oxide at high thermal budget is observed, whereas the N_2O oxide is found to maintain its structural integrity along the interface. The differences are shown in higher magnification in the STEM-HAADF micrographs in Figure 2(e,f). The superposition between a region displaying contrast from SiOx and a region with a pinhole in Figure 2(f) indicates that the UV-O_3 layer is only partially disrupted.
Characterization of the same samples by X-Ray reflectometry (XRR) was also used to study the differences in the two oxide layers on a larger scale, confirming the HR-TEM results. Furthermore, chemical analysis conducted by depth-dependent X-Ray photoelectron spectroscopy (XPS) reveals that the N_2O oxide is richer in oxygen and contains a higher amount of nitrogen compared to the UV-O_3 one, as shown in Figure 3. These distinguishing characteristics can be directly linked to the enhanced stability exhibited by the N_2O oxide under higher annealing temperatures and extended dwell times, in agreement with previous research [2], [3].

This study highlights the effectiveness of the employed characterization techniques as a robust method for analyzing multi-layer stacks, particularly well-suited for nanoscale thin films. By integrating more invasive techniques such as TEM and XPS depth-profiling with the non-destructive approach of XRR, it is possible to characterize large sample areas while also resolving layers at the atomic scale. This combined approach allows the analysis of full c-Si/SiOx/poly-Si stacks after RTP, closely resembling structures used in solar cell applications, thereby providing valuable insight for further development and application of such contacts. This approach differs from the majority of similar studies in literature that primarily focus on characterization of as-deposited oxide layers [3]–[5].

Poster Group 2

Full-area passivating contacts utilizing SiOx/poly-Si stacks are a critical component for the coming generations of high-efficiency industrial silicon solar cells, replacing the previous mainstream technology called passivated emitter and rear cell (PERC). In this work, the metallization of p-type passivating contacts formed via a rapid thermal processing (RTP) step is investigated. Metallization of poly-Si layers typically involves silver-based pastes for both sides of the cell, leading to higher production costs compared to PERC, which use Ag only on one side. Moreover, concerns over the long-term availability of silver prompt the search for more abundant alternatives to reduce costs and ensure sustainability in solar cell production [1].

The formation of Al-Si contacts, which results in the creation of µm-deep spikes within the c-Si wafer, has been well-documented in the context of PERC cells [2], but it has not been investigated thoroughly for poly-Si layers. The feasibility of utilizing aluminium pastes to establish contact with p-type poly-Si layers was explored in a prior study [3]. Characterization of the microstructure of the contacts after firing at different temperatures highlighted the numerous interactions taking place between the aluminium and the different layers in the stack (SiNx, poly-Si, SiOx and the c-Si wafer), which create a challenging trade-off between achieving a good electrical contact while retaining high passivation quality. Moreover, it was demonstrated that, for more fundamental studies, it is possible to replace the paste with evaporated Al, simplifying the analysis [3].

To gain further insight into the reaction mechanisms, this works focuses on characterization of the samples during in situ heating by scanning transmission electron microscopy and energy dispersive X-ray spectroscopy (STEM/EDX) for temperatures below 650°C. The sample fabrication steps, structure and the heating profile applied during characterization are depicted in Figure 1. The reactions observed during the heating process are represented schematically in Figure 2. The initial phase involves Si out-diffusion into the Al from the underlying layers (Figure 2(b)), followed by Al diffusion at higher temperatures. The latter appears to occur initially vertically through regions with reduced density or thickness in the parasitic SiOx layers present at the various interfaces, and subsequently laterally within the SiNx and poly-Si layers (Figure 2(c)). Here, the oxide layers at the interfaces function as diffusion barriers, promoting lateral rather than vertical Al diffusion. The nc-Si(i) layer exhibits similar behaviour, showing no discernible reaction with Al at this stage (T < 500°C), as visible in Figure 3. This is likely due to the enhanced crystallinity of the nc-Si(i) compared to the poly-Si(p) layer, which has been reported to hinder reactions with Al [4]. In the final stages of the process (Figure 2(d) and Figure 4), Al diffuses into the nc-Si(i) layer, eventually reaching the wafer interface where it accumulates at the thin SiOx and creates pinholes within the SiOx layer. These observations can explain the passivation degradation observed in previous work at relatively low temperature

(500-600°C), well below the threshold for formation of the µm-deep Al spikes. Furthermore, this study provides insights into potential avenues for improvement, such as enhancing the crystallinity of the poly-Si layer or substituting the SiOx with a layer less reactive with Al.

Study of skyrmions in ferromagnetic metallic superlattices using in situ Lorentz magnetic methods

Anaïs Fondet[1], Dr Thomas Blon[2], Dr Anne Bernand-Mantel[1], Dr Christophe Gatel[1]
[1]CEMES-CNRS, Toulouse, France, [2]LPCNO, Toulouse, France

PS-08 (1), Lecture Theater 2, august 27, 2024, 10:30 - 12:30

Background incl. aims
Magnetic skyrmions, which consist of local swirls of spins, are a prime example of topologically nontrivial spin textures. Nanoscale isolated skyrmions exist at low temperature in bulk chiral materials, while in thin films and multilayers, room temperature (RT) stable skyrmions exhibit intermediate sizes ranging between 50 nm to a few µm. Ferromagnetic metallic superlattices are materials which are promising for the development of RT nanoscale skyrmions due to the high tunability of their properties. There exist a large number of experimental studies reporting the observation of stripe domains and skyrmion bubbles in metallic multilayers, for example Pt/Fe/Ir[1] and Ta/Co/Pt[2]. It is well understood that these skyrmions and stripes are created by a combined action of the stray field effect and the Dzyaloshinskii-Moria interaction (DMI)[3]. These non-collinear spin structures can also be easily simulated numerically [2]. However, in a system with a high number of degrees of freedom, the quest remains open regarding how to optimize the parameters to obtain the most compact and stable skyrmion and the development of adequate analytical tools could lead to breakthrough and transform this quest from a random walk to a guided tour. Many experimental techniques have been used throughout the years in order to study skyrmions, including Magnetic Force Microscopy[4], soft-x-ray microscopy[1] and Magneto-Optical Kerr Effect (MOKE) microscopy [5] among others. But quantitative nanoscale studies on the conditions of skyrmion nucleation remains of primary importance. In this study we chose to study skyrmions in a classical [Pt/Co/Ta]n metallic superlattices system, n being the number of repetition of the tri-layer.
Methods
Samples were fabricated by magnetron sputtering, and studied using Lorentz Transmission Electron Microscopy (LTEM) in Fresnel mode combined with electron holography (EH). LTEM in Fresnel mode offers an easy and straightforward method for a semi-quantitative study of the local magnetization, well suited to the observation of skyrmions. We aimed to explore the magnetic phase diagrams of our multilayered magnetic system by developing an automatized process to record magnetic images with in situ application of magnetic field through the control of the objective lens and modulation of the temperature using a dedicated sample holder. In parallel, we used electron holography (EH) which allows to reach higher spatial resolution (up to 0.5 nm) and obtain quantitative magnetic measurements. Our approach is combined with MOKE, theoretical models and numerical simulations (using Mumax3).
Results
In this system, RT skyrmionic bubbles as small as 50 nm have been observed when the Co thickness was tuned close to the spin reorientation transition[2]. In our study, we fixed the Co thickness at 0.8 nm and we tuned the thickness of the total system by varying the number of repetitions n of the Pt/Co/Ta tri-layer. This allows us to tune selectively the effect of the stray field while keeping roughly constant the system intrinsic parameters (magneto-crystalline anisotropy, saturation magnetisation, DMI). We were able to image the magnetic micro-structures of [Pt/Co/Ta]n multilayers with various different number of repetitions in LTEM and MOKE (Figure 1a). We conducted an experimental study of the stripe domain structures as a function of the multilayer total thickness, see Figure 1b, and

when applying a magnetic field (using the objective lens), we studied the formation process of magnetic skyrmions, the stripe-skyrmion transition, and the presence of skyrmion lattice or isolated skyrmions in certain samples. We could correlate the magnetic contrast observations with applied field to the magnetic hysteresis obtained from VSM measurements. We also studied the influence of the temperature on the stripe pattern and on the formation of skyrmions, from which we could elaborate experimental phase diagrams coupled to theoretical diagrams, based on skyrmionic bubble model (Figure 2). Finaly, we performed EH experiments at the state-of-the-art, combining high spatial resolution with a dedicated Lorentz stage, direct electron detector with the K3 camera and long exposure time up to 4 mn thanks to the dynamical correction of instabilities. We were able to recover the magnetic phase of the Néel type skyrmions up to few nanometers of spatial resolution, and to observe the detailed stripe-to-skyrmion transition with external applied magnetic field (Figure 3). We will detail the magnetic processes which has been deduced from such observations combined with simulations.

Conclusions

Our experimental study focused on [Pt/Co/Ta]n metallic superlattices, investigating the manipulation of their properties by varying the number of repetitions (n) of the tri-layer. Through spatially resolved magnetic measurements using magneto-optic techniques and transmission electron microscopy methods combined with in situ experiments, we could explore the stripe domain structures and skyrmion formation as a function of total thickness, the applied magnetic field and varying the temperature. Our findings give new insights of the stripe-skyrmion transition and temperature's influence on these phenomena, supported by experimental phase diagrams and theoretical models. Additionally, we studied Néel-type skyrmions structure using advanced EH observations, achieving a very high spatial resolution and observing detailed transitions from stripe to skyrmion configurations under external magnetic fields. Our study provides significant contributions to understanding the magnetic behaviors of skyrmions in metallic superlattices by combining TEM magnetic imaging and MOKE, correlated to micromagnetic simulations, stripe domain and skyrmion models.

IM-01, Lecture Theater 1, august 26, 2024, 14:00 - 16:00

Background incl. aims
Fivefold symmetry is mysterious in crystallography because it lacks translational invariance and periodic structures. We cannot fill two-dimensional (2D) planes with regular pentagons or make an icosahedron with regular tetrahedra (Figure 1a-b). Multiply twinned particles (MTPs) have attracted attention since their discovery because of their excellent optical and catalytic properties, crystallographically forbidden fivefold symmetry and associated lattice misfit strain. Icosahedral MTPs composed of fivefold twinned tetrahedra have broad applications and the researchers have observed from 2D perspective for decades [1-7]. Electron tomography offers a method to image internal distortions and visualize successive twinning in three-dimensional (3D) [8-9]. However, the atomic misfit, the associated strain relief mechanism, and the bridging solid-angles in icosahedral MTPs are not yet quantitatively understood in 3D, primarily due to a lack of experimentally obtained 3D atomic structures of MTPs.
Methods
Gold MTPs, coated with a thin shell of palladium, and Pd@Pt core-shell MTPs were synthesized and deposited on thin Si3N4 film for high resolution imaging. We employed atomic resolution electron tomography to determine the 3D atomic coordinates of the MTPs. In short, the tomographic tilt series were acquired with aberration-corrected STEM in annular dark-field mode. After drift correction and denoising, we reconstructed the tomographic tilt series using the real space iterative reconstruction (RESIRE) algorithm; we then traced and classified the 3D atomic coordinates and chemical species.
Results
Here, we determined the 3D atomic structures of Janus icosahedral nanoparticles using atomic resolution electron tomography. A geometrically fivefold face (C5 side) consistently corresponds to a less ordered face (C5’ side) like two hemispheres (Figure 1c-d). We found that the 3D angular deficiency is compensated by insertion of edge dislocations and amorphization of several tetrahedra. The disordered amorphous domain with the largest solid angle is 14.6° larger than the ideal fcc domain, relaxing a large amount of strain and filling the largest angular defects (Figure 1e-h). Edge dislocations fill the angular deficiency near the axis. Our research has unveiled, for the first time, how the spatial gap of the icosahedron is compensated at the 3D atomic scale and provide a completely new insight on atomistic models for the modelling of formation mechanisms of fivefold and icosahedral twinned structures by molecular dynamics as well as computer simulations of lattice distortions and defects..
Conclusion
The novel physical insights are 1). We clearly show that the 3D angular deficiency is compensated by insertion of edge dislocations and amorphization of several tetrahedra instead of homogeneous dilatation in all the twenty tetrahedra. 2) Many structural characteristics of the icosahedral MTPs are

divided into two groups spatially distributed in two hemispheres of the MTPs, such as the bond orientation order parameters, solid angle, and the number of atoms. The twelve fivefold axes are not uniformly distorted; edge dislocations are preferably distributed in one side of the particle. Our observations provide a completely new insight on atomistic models for the modelling of formation mechanisms of fivefold and icosahedral twinned structures by molecular dynamics as well as computer simulations of lattice distortions and defects.

In the field of battery electrode materials, the presence of multiple phases undergoing structural modifications poses a significant challenge, as it can drastically impact battery performance and durability. These phases introduce complexity to the electrochemical processes that occur during charge and discharge cycles. As Na ions transfer between the positive and negative electrodes, structural transformations within the electrode materials take place. The spatial distribution of Na ion occupancy inside the crystal host leads to phase transitions and structural rearrangements, a phenomenon exacerbated by the co-existence of multiple phases related to multiple electrochemical activations. Each phase exhibits distinct electrochemical properties and undergoes different structural modifications during cycling, collectively influencing overall battery performance1. Therefore, it is imperative to characterize and understand the individual contributions of these phases and their spatial distribution.

For this purpose, we employed scanning transmission X-ray microscopy (STXM), offering a spatial resolution of 30 nm, coupled with X-ray absorption spectroscopy technique (XAS) at the HERMES beamline of the SOLEIL Synchrotron. Our focus was on the chemical evolution of Na3V2(PO4)2F3 (NVPF) upon charge/discharge cycles. These NVPF cathode samples underwent electrochemical cycling (versus hard carbon) processes to achieve various Na contents, specifically Na2.5V2(PO4)2F3, Na2V2(PO4)2F3, Na1V2(PO4)2F3, and Na0.3V2(PO4)2F3. NVPF is a promising material for the next generation of sodium batteries, but its complex phase behavior makes it difficult to characterize using traditional methods2. Therefore, the main objective of our study is to develop a novel approach for processing STXM-XANES data to obtain phase maps within individual crystals of the NaxV2(PO4)2F3 (x = 0.3, 1.0, 2.0, 2.5, 3.0) cathode material.

To achieve our objective, we developed a Python-based solution that leverages machine learning algorithms, i.e. non-negative matrix factorization (NMF) and the Pearson correlation coefficient (PCC). This approach enabled us to identify various sodium occupancy phases within individual Na3V2(PO4)2F3 crystals, providing detailed phase maps based on X-ray absorption edges of V and O modifying with the state of charge. With indirect observation in variations in sodium content inside individual crystals, our study offers fundamental insights into sodium-ion diffusion processes, which are essential for guiding the development of advanced cathode materials for the next generation of Na-ion batteries.

In parallel, we conducted a structural study based on electron diffraction using four-dimensional scanning transmission electron microscopy (4D-STEM) automated crystal orientation mapping (ACOM), on the same individual crystals as in STXM3. To facilitate this process, we developed the ePattern4 code to index diffraction spots and reduce the noise in large datasets. By combining ePattern with the software ASTAR (Nanomegas), a pattern matching approach for crystal orientation and phase determination, we generated phase maps based on the structural information of our sample. The close lattice parameters of the de-sodiated phases raise questions about the phase map reliability.

In this study, we developed a Python solution that allowed us to obtain phase maps and reliability maps for the STXM-XANES data, offering insights into the confidence level of our phase mapping results. These maps provide valuable information about the accuracy and reliability of the identified phases within the sample. Our study demonstrates the effectiveness of combining advanced analytical techniques with machine learning algorithms to characterize phase heterogeneities within battery electrode materials. By developing a novel approach for processing STXM-XANES data, we were able to gain detailed insights into the phase behavior of Na3V2(PO4)2F3 cathode material. These insights are crucial for advancing the development of sodium-ion batteries, paving the way for the design and optimization of electrode materials with improved performance and durability.

In and ex situ (S)TEM manipulation of 2D materials without air exposure

Manuel Längle, Alberto Trentino, Georg Zagler, Barbara Mayer, Clemens Mangler, Harriet Ahlgren, Kimmo Mustonen, Toma Susi, Jani Kotakoski[1]
[1]University of Vienna, Vienna, Austria

PS-01 (1), Lecture Theater 3, august 28, 2024, 10:30 - 12:30

Graphene—the one-atom-thick sheet of carbon—is the most famous of 2D materials due to its unique electronic properties and mechanical strength. However, its chemical inertness makes graphene also an excellent nearly electron-transparent support for other materials, nanostructures and even active individual atoms for example for single-atom catalysis. Similarly, the insulating counterpart of graphene, hexagonal boron nitride, has emerged as an interesting host for single-photon emitters realized as point defects. Unfortunately, since 2D materials consist solely of surface, they are easily obscured by the ubiquitous surface contamination that makes working with them challenging.

In this contribution, I will demonstrate that defect-engineering of graphene [1] enables its substitutional heteroatom doping [2] and growth of nanoclusters with a well-defined concentration and a narrow size distribution, as well as the direct correlation of its atomic structure and mechanical properties. I will further show that hBN can similarly be tailored with low-energy noble gas irradiation to create point-defects in a controlled manner. The defect manipulation is carried out in a vacuum system [3] that is directly connected to a Nion UltraSTEM 100 microscope, which allows sample cleaning, manipulation, and atomic-scale imaging and spectroscopy without air exposure. The defects are imaged via annular dark field imaging and the impurity atom identification is confirmed by electron energy loss spectroscopy.

The methodology employed here can be easily extended to other 2D materials, and is expected to lead to structures with potential applications in plasmonics, quantum information technology, sensorics and catalysis.

Deformation mapping in Lorentz transmission electron microscopy images of magnetic skyrmion lattices

Dr. Thibaud Denneulin[1], Dr. András Kovács[1], Pr. Rafal E. Dunin-Borkowski[1]
[1]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons and Peter Grünberg Institute, Forschungszentrum Jülich, Jülich, Germany

Poster Group 1

Background
Magnetic skyrmions are quasi-particles with a swirling spin texture. In chiral magnets, skyrmions are stabilized by the balance between the exchange interaction and the Dzaloshinskii-Moriya interaction. They have raised interest because of their potential applications in the field of spintronics, for instance in racetrack memories where they are treated as information carriers [1]. Axially symmetric chiral skyrmions usually form 2D hexagonal close-packed lattices [2]. Similarly to atomic lattices, skyrmion lattices can exhibit local deformations and crystalline defects such as dislocations and grain boundaries depending on the geometric constraints and the external magnetic fields [3]. Measuring deformations in skyrmion lattices is important to understand the interplay between the lattice structure and external influences.
In previous studies, skyrmion lattice deformations were investigated using real-space methods applied to Lorentz transmission electron microscopy (LTEM) images, which involves detecting intensity maxima or minima, finding nearest neighbors and calculating inter-skyrmion distances [3,4]. Here, we investigate the applicability of geometric phase analysis (GPA) [5]. GPA is a lattice deformation analysis technique based on Fourier transforms primarily used in high resolution TEM images. Compared to real-space methods, GPA is straightforward computationally because there is no need to detect individual maxima and perform any pixel-to-pixel operation. A Fourier transform of the image is first calculated and numerical apertures are applied to a pair of Bragg spots with non-colinear reciprocal lattice g-vectors. After inverse Fourier transform, the geometric phase term $\varphi(r)=-2\pi g.u(r)$ associated to each g-vector is retrieved, where u is the displacement vector. The deformation fields are then obtained using differentiation of the displacement fields.

Methods
Experiments were carried out using a TFS Titan TEM equipped with a Schottky field emission gun operated at 300 kV, a CEOS image aberration corrector and a 4k*4k Gatan K2-IS direct electron detector. The microscope was operated in Lorentz mode by using the first transfer lens of the aberration corrector as the main imaging lens. The objective lens was used to apply magnetic fields perpendicular to the sample which were precalibrated using a Hall probe. A liquid-nitrogen-cooled specimen holder (Gatan model 636) was used to vary the sample temperature. The Digital Micrograph software and a GPA plugin were used to calculate deformation maps. A TEM lamella of FeGe was prepared from a bulk crystal using focused Ga+ ion beam sputtering in a scanning electron microscope (FIB-SEM) FEI Helios dual-beam platform.

Results
Figure (a) shows an example of Lorentz TEM image of a skyrmion lattice in a 150 nm thick FeGe lamella recorded at 230 K with a defocus of 800 µm and in the presence of an external magnetic field of 145 mT. Normally, each skyrmion has 6 neighbors in a hexagonal lattice. However, it is common to observe dislocations formed by pairs of 5 and 7-coordinated skyrmions. Such a dislocation is present

in the middle of the image and it is magnified in Fig. (b) where the heptagon and the pentagon have been drawn. A Burgers circuit has also been traced to show the Burgers vector b. Figure (c-f) shows the experimental deformation fields calculated using GPA and Fig. (g-j) shows the corresponding theoretical deformation fields calculated from linear elastic theory. The horizontal deformation εxx, along the direction parallel to the Burgers vector, shows a butterfly shape with negative (compressive) deformation in the top part of the image and positive (tensile) deformation in the bottom part. The vertical deformation εyy shows a three-fold symmetry with alternating negative and positive deformations around the dislocation core. The shear deformation εxy and the rigid-body rotation ωxy show primarily loops oriented along the horizontal direction, parallel to the Burgers vector. Visually, the shape of the experimental and theoretical deformation fields is in good agreement even though the experimental images show some random fluctuations. To provide a quantitative comparison, Fig. (k-n) shows the difference between the experimental and theoretical deformation fields. The standard deviation δ was calculated and is indicated on each image. The region in the vicinity of the core (approximately 150 nm around the core, as indicated by the dotted square) was excluded from the measurement. The small values of δ ≈ 1% or 1° indicate a good quantitative agreement.

Conclusions

We have studied deformations in skyrmion lattices in a sample of FeGe by applying GPA to Lorentz TEM images. Deformation fields measured around a single dislocation were found to be in good agreement with deformation fields calculated from linear elastic theory. In the conference presentation, we will also show rotation fields measured at the boundaries between crystal grains and compare them with angles calculated from the density of dislocations. We will also discuss the evolution of deformation fields in applied magnetic fields series of LTEM images and explain how to calculate an orientational order parameter to study the evolution of the disorder. The influence of potential artifacts such as geometric distortions and large defoci will also be discussed.

PS-05 (2), Lecture Theater 1, august 28, 2024, 14:00 - 16:00

Background incl. aims
The unique properties of nanomaterials are being leveraged to create textiles with enhanced fabric properties, a trend exemplified within the production of face masks since the onset of the Covid-19 pandemic. The use of silver (Ag) is advertised in several commercially available face masks because of its biocidal properties, claiming a higher form of protection to the wearer. The silver biocide can present itself either in ionic form, nanoparticle (NP) form or as part of a composite material, however, this is not always correctly advertised[1]. In addition, the presence of titanium dioxide (TiO_2) nanoparticles, acting as a whitening and mattening agent, in synthetic fibres applied in face masks has been demonstrated[2], even when no specific information was provided on their packaging. Since TiO_2 is a suspected carcinogen (IARC 2B) and potential negative health effects are reported for nano-silver[3], their use in masks raises health concerns because of the potential inhalation exposure to nanoparticles. This emerging area of concern lacks methodological development regarding the assessment of inhalation exposure to nanoparticles during mask use. To assess the potential of particle release and associated risks, at first a detailed characterization of the localization and the form of nanomaterials within the mask is necessary. This work applies scanning transmission electron microscopy (STEM) coupled with energy-dispersive x-ray spectroscopy (EDX) on a set of 10 face masks. The method is evaluated in terms of ability to distinguish different nanoforms, to measure particle properties (size/shape/agglomeration state) important in the context of risk assessment in line with the European Union's regulatory framework and to assess potential release of NP.
Methods
A set of 10 face masks, including community, surgical and FFP2 masks, was characterized. 6 masks, where the application of biocides (5 Ag, 1 unspecified) was advertised, and 4 masks, demonstrated to contain TiO_2 (2 of them also had Ag advertised) were selected to assess the form, localization and measurement of Ag (and other possible biocides) and TiO_2, respectively. Since the masks usually consist of multiple layers of fabric, at first the layer with the highest Ag or TiO_2 content was identified using inductively coupled plasma assisted optical emission spectroscopy or mass spectroscopy and selected for subsequent STEM analysis. The mask was disassembled and a piece of 1 mm x 5 mm was cut from the selected layer. The preparation of TEM specimens from the pieces of mask followed the methodology described in Wouters et al.[4] Ultra-thin sections of the textiles were prepared by embedding them in epoxy resin, followed by ultra-thin sectioning using ultramicrotomy. Subsequent STEM-EDX analysis was carried out on a Talos F200S transmission electron microscope equipped with a high angle annular dark field detector and a Super-X EDX detector (Thermo Fisher Scientific, Eindhoven, The Netherlands). Imaging and image analysis was done using Velox software (V3.11, Thermo Fisher Scientific).
Results

In 5 face masks, a form of (nano)silver could be identified. In each of those masks, the silver biocide presents itself under a different form: (i) a silver-silica NP composite, (ii) a reaction mass of silica, titanium dioxide and silver chloride NP (see graphic), (iii) a silver-zincoxide NP composite, (iv) nanoscale silver precipitation on a mineral complex and (v) NP containing a combination of silver and sulfur or silver and tin. In 4 out of 5 cases, the identified biocide form is not matching the advertized description, which is often ambiguously reported or lacks the mention of a 'nanoform'. In cases (i) and (iii) the silver biocide is embedded within the fibres, while in the other three cases it is at least partly present on the surface of fibres. The amount of silver-containting particles detected in each sample is too low to build a statistically relevant size distribution but their sizes range from 5-200 nm and they have a spheroidal shape.
Even though only 4 masks were selected for evaluation of incorporated TiO_2 particles, TiO_2 was detected innine masks. This was notmentionedon the packaging or in the provided technical information. The TiO_2 appears in the form of aggregates and agglomerates of spheroidal (nano)particles which are embedded within the fibres, and some are also present on the edge of fibres. A preliminary quantitative analysis of TiO_2 in selected samples, reveals an average aggregate/agglomerate size of 186 nm and an average constituent particle size of 100 nm in terms of the minimum Feret diameter, in agreement with the typical textile grade TiO_2[5].
Three masks are found to consist of fibres with a (partial) coating of NP. In one mask this coating consists of a mix of TiO_2 and AgCl NPs embedded within silica (see graphic). The mask with unspecified biocide consists of fibres with a partial coating of agglomerated silica NP with constituent particle sizes on the order of a few tens of nm. And lastly, one mask, which applies a photocatalytic activation of the biocide, consists of a mix of polymer fibres and silica-containing, fibre-like structures. The latter ones have agglomerated TiO_2 particles attached to them, with constituent particle sizes varying from approximately 10 to 50 nm, i.e. smaller than the textile grade TiO_2 reported before. These three masks are considered to be most prone to partice release, based on the localization and amount of observed nanomaterial.
Conclusion
STEM-EDX proves itself as a valuable methodology to allow identification of the type of biocide, the localisation of the (nano)particles and their size measurement within fibres of face masks. Our analyses reveal that packaging labels are often not accurately reporting the type of biocide or nanoparticles applied within the product, highlighting the need for regulatory control. The presence of NP on the fibre's surface presses for investigations of potential release of particles under realistic usage conditions, which will be explored in the next stage of the project.

This project is funded by the ANSES National Environmental Health-Work Research Program with the support of the ministries responsible for the environment, agriculture and labor (ANSES-22-EST-023).

Strain Sensitivity of STEM-GPA-based Strain Map

Bumsu Park[1], Minsik Kim[1], Jiwon Jeong[1], Sungho Lee[1]
[1]Samsung Electronics Advanced Analysis Science & Engineering Team, Hwaseong-si/Samnsungjeonja-ro, Republic of Korea

PS-03 (1), Lecture Theater 2, august 29, 2024, 14:00 - 16:00

Background
Strain engineering, one way to improve the performance of semiconductor devices is to apply strain intentionally to improve device characteristics. In addition, as the size of semiconductor devices decreases to improve the integration density, it has become important to analyze the strain distribution in localized areas that directly affect device performance. The GPA-based strain analysis method is widely used to analyze the strain, but there has been no clear numerical verification of the strain detection limit. In this study, we clarified the empirical limitations of the GPA method and proposed optimal experimental conditions for its application to real devices.

Methods
We used artificial STEM-ADF images with in-plane strains of 1%, 0.1%, and 0.05% to compare the strain values detected by changing the pixel resolution of each image with the actual strain values. Each image was tested up to a data binning factor of 2n (n = 1 to 6) in the original image. In addition, we considered Poisson noise to mimic the real STEM imaging conditions. Finally, we used STEM-ADF images obtained from a silicon device with various pixel resolutions and compared the strain mapping results.

Results and Conclusions
The strain analysis results using images containing 1%, 0.1%, and 0.05% strain without considering Poisson noise showed that the detected strain is 1 ± 0.001%, 0.1 ± 0.002%, and 0.05 ± 0.01% respectively for images with a pixel resolution of 22 pm or less. When considering Poisson noise, a comparison of the standard deviation (SD) of the strain values showed that for spatial resolutions of 22 pm/px or higher, strains of 1% and 0.1% can be detected with a reliability lower than 0.02% of SD. In the case of 0.05%, the strain value is detectable up to a spatial resolution of 22 pm/px, but the strain precision deteriorates from 0.04% to 0.7%. Interestingly, as the binning factor increases, a periodically repeating local strain undulation was observed on the strain map. This is due to the difference in distance between atoms and periodicity between pixels, resulting in a Moiré pattern that degrades the accuracy of the strain map. In this presentation, I will additionally share the results of strain maps obtained through GPA on real devices and will compare strain maps obtained by 4D-STEM.

Figure1. (a) Simulated Si (Z.A = [110]) STEM-ADF images containing 0.05% in-plane strain with various binning factors. Corresponding in-plane strain maps (b) without and (c) with Poisson noise.

A retractable, compact Secondary Electron Energy Spectrometer attachment for Scanning Electron Microscopes

Wenzheng Cao[1], Prof. Anjam Khursheed[1]
[1]Politecnico di Milano, Milan, Italy

Poster Group 1

Background:
Energy spectrometers, such as the EDS (Energy Dispersive X-ray Spectroscopy) attachment in a Scanning Electron Microscope (SEM), have been widely used in material science for quantitative elemental analysis and contamination identification. However, EDS typically requires a minimum accelerating voltage of 6 kV and a high current primary beam to generate sufficient characteristic X-rays for accurate analysis. Unfortunately, these high voltages and currents can lead to charging effects in non-conductive materials like semiconductors and biological samples, hindering the analysis process. Additionally, EDS provides only microscale resolution due to X-rays being generated from a relatively large volume. As an alternative, Secondary Electron Energy Spectroscopy (SEES) has emerged as a promising method for achieving nanoscale quantitative material analysis using a low-voltage SEM (LVSEM) [1,2].
Methods:
A novel electric sector compact Secondary Electron Energy Spectrometer was designed and optimized using direct ray tracing of electrons through a Finite Element Method (FEM) field distribution. Based on the optimized design, a prototype was constructed and tested within a commercial SEM using a 1 to 2 KV low-energy primary beam. Various materials, including gold, copper, and silicon, were examined to assess the spectrometer's elemental identification capabilities.
Results:
The simulation results predict that the spectrometer achieves a relative energy resolution of 1.54% for a polar entrance angular spread of 20°, azimuthal angular spread of 150°, and a working distance of less than 10 mm. Experimental results confirm that different elements can be easily distinguished based on their secondary electron energy spectra FWHM and peak position, as shown in the graphic, in which test experimental SE energy spectra of gold and copper samples are presented. Furthermore, due to its compact size, the spectrometer can be conveniently installed or removed.
Conclusions:
A compact/retractable electric sector secondary electron energy spectrometer attachment for SEMs has been designed, and is predicted to have high energy resolution and high collection efficiency. This new attachment can be seamlessly integrated into the SEM chamber, greatly enhancing the capabilities of the SEM system with its quantitative elemental analysis and material science ability. Furthermore, 2D mapping and dopant profiling are also expected in the near future.

Approaching picosecond temporal resolution in off-axis electron holography

Dr. Tolga Wagner[1], Hüseyin Çelik[2], Simon Gaebel[3], Dirk Berger[4], Christian M. Günther[4], Ines Häusler[1], Sebastian Siewert[2], Michael Lehmann[2], Christoph T. Koch[1]
[1]Department of Physics, Humboldt-Universität zu Berlin, Berlin, Germany, [2]Institute of Optics and Atomic Physics, Technische Universität Berlin, Berlin, Germany, [3]Max-Born-Institut, Berlin, Germany, [4]Center for Electron Microscopy (ZELMI), Technische Universität Berlin, Berlin, Germany

Poster Group 2

In the course of new technological and instrumental possibilities, time-resolved investigations in transmission electron microscopy are currently gaining particular relevance [1]. For phase-resolving methods, however, there are hardly any realizations for the investigation of dynamic processes on ultrashort time scales, although these are of great importance, especially for in-operando investigations of dynamic potential distributions in nanostructures (e.g. switching semiconductor or magnetic topological nanostructures).
Recently, interference gating (or iGate) has emerged as a simple, but robust method to address this circumstance [2]. It is based on the intentional destruction of the interference pattern for a large part of a measurement, utilizing short undisturbed time periods (called gates), which are synchronized to a periodic process under investigation, to generate time-resolved interferometric information. In particular, the simple technical realization of the method (only a two-channel signal generator, two coaxial cables, an dedicated aperture holder and an electrical biasing sample holder are required) enables low-barrier access to the investigation of ultrashort phenomena on existing instruments [3]. Through continuous improvements in sample preparation, automated measurement and reconstruction routines, control signal design, and the necessary electron-optical components, the time resolution achievable with iGate has recently broken through the picosecond barrier. By an application to silicon diodes, switching at repetition rates in the MHz range, variations of the local capacitance C(x,y,t) could be observed and the cause of the anomalous (MOS-cap-like) switching behavior of a defective semiconductor nanostructure was revealed [4]. A schematic representation of the experiment is illustrated in the accompanying figure. The nanostructured diode sits in between two extended metallic contacts, forming an overarching electrical system (e.g. parallel connected capacitances in vacuum C(x,y) and the diode C(x,y,t)).
In addition, the method itself could already be implemented in transmission electron microscopes in further laboratories in very short time frames (less than a work day), whereby the FPGA-based conversion of a JEOL JEM-2200FS into a versatile phase-resolving instrument with sub-nanosecond temporal resolution is discussed here in detail. The presented results will highlight the advantages of image-based investigations of projected dynamic potential distributions with nanometer and sub-nanosecond resolutions and their application to materials science problems, and pave a new path for decoding dynamic processes and their physical causes directly at the point of their occurrence.

Synthetic data generation and Mask-RCNN for Transmission Electron Microscope Image Segmentation

Natalia Da Silva De Sa[1], Dr. Andrew Stewart[2]
[1]University of Limerick, Limerick, Ireland, [2]University College London, London, United Kingdom
IM-10 (2), Lecture Theater 3, august 29, 2024, 14:00 - 16:00

Background incl. aims
The rapid advancement of neural networks (NN) has led to a diverse array of innovations, including autonomous driving, image and text generation. Notably, within image processing, object detection and classification has been significantly improving with a variety of NNs leading the way, particularly U-Net, Fast-RCNN, Mask-RCNN. A significant challenge while training a NN is the substantial volume of training data required to achieve satisfactory results. ImageNet or COCO are typical datasets, with 14M and 200K labelled images (image and ground truth pairs), respectively, used to train NNs to detect everyday objects, people and animals within images. The Transmission Electron Microscope (TEM) field stands to benefit from machine learning image analysis techniques, which can reduce the time and effort of researchers analysing images, especially for particle size and morphology. Furthermore, automation of image analysis will lead to an increase in reproducibility when compared to manual analysis, however, there is a lack of publicly available data which is segmented and labelled appropriately for such applications. Here we present an alternative approach using synthetic data as a method for overcoming the lack of segmented and labelled data, which differs from simulated data and is a pictorial representation rather than a specifically generated simulation of a TEM image and use Mask-RCNN for instance segmentation, a form of image segmentation that detects individual objects in an image. The application shown here is for nanoparticle analysis. The principles can be generalised to all image data produced in a transmission or scanning electron microscopes.
Methods
Our research introduces an innovative approach to generating synthetic images for training machine learning algorithms in nanoparticle detection and classification. Unlike traditional simulation methods (multislice, Bloch waves), our method utilises Python packages to generate images, bypassing the need for costly computing resources. We illustrate this approach through two distinct examples: the creation of polylatex spheres and silica particles on holey carbon substrates with ultra-thin continuous carbon layers and expand to gold nanoparticles. By randomising various parameters such as magnification, particle size, illumination, and contrast, we generate synthetic data for training an instance segmentation machine learning algorithm.
Specifically, we employ a Mask-RCNN model pretrained on the COCO dataset and refine it using our synthetic transmission electron microscopy (TEM) images, a technique known as transfer learning. This approach significantly improves the model's performance by leveraging knowledge from a broader dataset for a specialised task. Subsequently, we apply the trained model to segment experimental TEM images sourced from Certified Reference Materials (CRMs), which are industry standards used for analytical validation and microscope calibration within the PAT4Nano standardization project. To enhance the algorithm's segmentation accuracy and reduce false positives, we explore augmenting the training data with synthetic particles overlaid on experimental TEM grid substrate images. The efficacy of this approach is demonstrated through comparative analysis and visualisation.

Expanding our data generation efforts, we simulate various scenarios including continuous carbon structures and diverse shapes of gold nanoparticles. Additionally, we adjust intensity values to fall within the 1-99 percentile range, further enriching the dataset. This augmented dataset is utilised to train a secondary Mask-RCNN model, which is then deployed for predicting segmentation of experimental images.

Results

Our evaluation of the models was conducted separately, utilising the Mean Average Precision (mAP) metrics. The Average Precision (AP) is quantified as the area under the precision-recall curve (PR curve), where precision denotes the ratio of true positive predictions to all predictions, and recall represents the proportion of correct positive predictions to all true positive cases. The mAP aggregates all AP values across various classes or categories. The initial model, trained on the polylatex/silica dataset with approximately 500 synthetic images, achieved a mAP of 0.40 when tasked with predicting 90 experimental images. Subsequent augmentation of the training dataset with an additional 500 synthetic images of particles overlaid on experimental backgrounds resulted in a notable improvement, raising the mAP to 0.80 for the same set of 90 experimental images. In parallel, the second model, trained on the gold nanoparticles dataset, attained a mAP of 0.84 when predicting 19 experimental images. Both model predictions were subjected to a minimum detection confidence threshold of 0.9. The graphics section visually depict the predictions generated by models 1 and 2, respectively, providing tangible insights into their performance.

Conclusion

Our research demonstrates the successful training of an instance segmentation algorithm using synthetic data generation, with notable enhancements are achieved by incorporating experimental backgrounds into the training process. Additionally, our findings illustrate the adaptability of the algorithm across diverse datasets characterised by varied backgrounds and particle shapes. Moving forward, our focus will centre on refining particle edge detections to achieve pixelwise accuracy and advancing nanoparticle measurement techniques. Furthermore, we aim to develop an open-source, user-friendly interface for the generation of synthetic data adaptable to a wide variety of transmission electron microscopy (TEM) data. This interface will include a built-in trainable model which can be tuned and refined with user generated synthetic data, facilitating broader accessibility to automated image segmentation for researchers with electron microscope data.

Probing chemical pathways in polymer membranes despite electron beam damage

Dr Catriona M. McGilvery[1], Dr Patricia Abellan[2], Prof Quentin M. Ramasse[3], Prof Alexandra E. Porter[1]
[1]Imperial College London, London, UK, [2]CNRS-Nantes University, Nantes, France, [3]SuperSTEM Laboratory, Daresbury, UK

Poster Group 2

Reverse Osmosis (RO) membranes are used for seawater desalination in the oil and gas industry. These membranes are made of a polyamide (PA) 'active' layer, around 100-500 nm thick, a polysulfone (PSf) support and a polyester backing layer. The PA layer is thought to control ion flow through the membrane yet very little is understood about how that is achieved at the nanoscale. A number of techniques have been used to try to characterise the PA layer but none of them have the spatial and energy distribution necessary for nanoscale chemical mapping. Here we test whether scanning transmission electron microscopy EELS (STEM-EELS) techniques can be used to map chemical functionality across flat RO membranes with nm-scale resolution. We argue that, despite the high electron flux required during acquisition, careful comparison to dose-managed control experiments on standards together with multivariate analysis post-processing techniques can be used to extract useful information about the distribution of functional chemistry from spectra acquired from damaged PA.

Practically, commercial RO membranes are very rough making them difficult to characterise. For this reason, in-house prepared 10 nm thick PA membranes prepared via an interfacial polymerisation technique, were used for this study. STEM EELS studies were carried out on a Nion UltraSTEM 100MC 'HERMES' monochromated transmission electron microscope at SuperSTEM (Daresbury, UK). The microscope was operated at 100 kV with a probe size of 0.9 Å and convergence and collection semi angles of 31 and 44 mrad respectively.

First, chemical maps of C, N and O K-edges, the main components of the membranes, were obtained. From the nitrogen signal the exact width of the membrane could be established as N is only present in the membrane itself. Control beam damage studies were carried out on large areas (800 nm x 800 nm) of plan-view samples so that the degree of damage on the C K-edge could be assessed. The parameters required to avoid detection of beam damage effects were impractical for obtaining chemical information with a pixel size of 2 nm. However, with higher electron fluences (e.g. 3-10 x 107 e/Å2 per probe size or 6-10 x 103 e/Å2 per pixel size), whilst damage occurred to the carbon bonds, the dominant features in the fine structure of the C K-edge were in fact still present and variations could be mapped across the PA membrane with a spatial sensitivity of 2 nm. Application of multivariate analysis to the raw high electron fluence data made it possible to assign peaks related to specific co-ordination environments by comparison with the control data fine structure.

This work shows that despite severe electron beam damage evident by the loss of fine structure of the C K-edge, information about functional chemistry within the PA can still be achieved. This suggests that spectra obtained where the electron flux has been high, may still be interpreted provided care is taken to assess the extent of possible beam damage and carry out control experiments. With continued advancement of technologies such as stable cold stages, high frame

rate cameras and direct electron detection capabilities it should become easier to map functional chemistry across radiation sensitive soft materials with nm-scale high spatial and energy resolution.

Oxidation states of IrOx characterised by EELS and ED-PDF

Dr. Trung-Dung Tran[1,2], Mr. Dogan Ozkaya[1,2]
[1]Johnson Matthey Technology Centre, Reading, UK, [2]ePSIC, Diamond Light Source, Didcot, UK
PS-04 (4), Plenary, august 27, 2024, 14:00 - 16:00

Background incl. aims
The global interest in hydrogen as a primary fuel has been fostering fundamental research of IrOx (Iridium oxide) - the most stable catalyst known for water-electrolysis to produce hydrogen. The presence of Ir(IV)/Ir(III) redox coupling is crucial for Oxidation Evolution Reaction (OER) activity of IrOx while metallic Ir only plays a little role in the aspects of stability and conductivity [1,2]. However, spatial distribution of Ir(III) with respects to Ir(IV) in IrOx catalysts has never been demonstrated previously. This kind of distribution would not only be a clear picture showing how Ir(III) can work together with Ir(IV) in an active and stable catalyst but also provide guidance for chemical engineering in tuning the oxidation state configuration for higher performance-to-mass ratio of the catalyst material.
Methods
In this talk, we will present the oxidation states of IrOx characterised by STEM-based EELS and Electron Diffraction based Pair Distribution Function (ED-PDF). The EELS method is based on measuring the profiles of electronic excitations from 5p and 4f to 5d and above the Fermi level (O and N edges). The EELS experiments were designed to minimise the effect of thickness variation (that can alter the plasmonic background) while improving signal/noise and energy resolution for detailed electronic-structure profiles.
Beside EELS, Electron diffraction pair distribution function (ED-PDF) [3] is another capable technique for characterisation of Ir-O bonding and IrOx atomistic structures, especially amorphous IrOx [4].
Results
O&N-edge profiles for different Ir oxidation states are shown in Figure 1(a). As shown in Figure 1(b), the microscopic distribution of Ir(IV), Ir(III) and Ir-metal can be mapped thanks to the differences seen in the corresponding O&N-edge profiles. Complementary to the Ir O&N-edges, EELS of O K-edge can give information about the atomistic structures of different IrOx phases. Figure 1(c) shows that amorphous IrOx, hollandite-type IrOx and the rutile-type structure of IrO2 can be distinguished clearly by the hybridisation profile in the O K-edges.
Ir-oxide (both amorphous and crystalline) and Ir-metal can also be characterised by ED-PDF. Figure 1(d) shows different distribution profiles of interatomic distances (particularly Ir-O bonds and Ir-Ir metallic bonds) for rutile-type IrO2, amorphous IrOx and Ir-metal.
Conclusion
This work shows the powerful capability of EELS and ED-PDF for characterisation of IrOx. The importance of EELS combined with EDPF will also be discussed in the presentation.

Figure 1. (a) EELS O&N-edges of different Ir oxidation states; (b) EELS mapping of Ir(IV), Ir(III) and Ir(0)-metal; (c) EELS O K-edge of amorphous IrOx, hollandite-type IrOx and rutile-type IrO2; (d) ED-PDFs of amorphous IrOx, rutile-type IrO2 and Ir-metal.

Atom Probe Tomography experiments performed in a (Scanning) Transmission Electron Microscope

Professor Williams Lefebvre[1], Gérald Da Costa[1], Castro Celia[1], Antoine Normand[1], Charly Vaudolon[1], Aidar Zakirov[1], Juan Macchi[1], Mohammed Ilhami[1], François Vurpillot[1]
[1]Univ Rouen Normandie, INSA Rouen Normandie, CNRS, Normandie Univ, GPM UMR 6634, Rouen, France

IM-04 (2), Lecture Theater 1, august 27, 2024, 14:00 - 16:00

Background
Atom Probe Tomography (APT) is intrinsically a 3D characterization technique that provides tomographic reconstructions of materials with a near atomic scale resolution. For APT, specimens must be prepared as sharp needles. This is most of the time realized using FIB SEM and before analysis in APT, specimens can easily be characterized in a TEM or STEM using specific holders or protocols. Hence, correlative analysis by (S)TEM and APT gives access to a wide range of information about the specimen. Unrivaled spatial resolution of (S)TEM, availability of 4D-STEM or diffraction with the combination of the 3D composition fields accessible by APT hence leads to a better description of materials by the correlation of structural, physical and chemical characterization.
To make correlative analysis by (S)TEM and APT more accessible, efforts have been foreseen and made to join both techniques in a single instrument [1-4]. This work presents the main achievement of an instrumentation project started at GPM in 2014, which is the implementation of an Atom Probe in a commercial JEOL F2 (Scanning) Transmission Electron Microscope.

Methods
Specifics TEM holders were designed first for a JEOL 2010 TEM, on which they were tested, and then transferred to a JEOL F2 installed at University of Rouen in 2022. These holders offer the possibility to perform APT experiments either at room temperature or cryo temperature (78K measured at the tip). They accept APT specimens which can be polarized with a positive voltage up to 8 kV. Electrostatic pulses are superimposed to trigger field evaporation with a pulse repetition rate of 20 kHz. The APT detector consists in an advanced-delay line setup, mounted on a port facing the goniometer of the microscope.

Results
The figure below shows the setup realized in the framework of this project. The ion sensitive and time resolved spatial detector is mounted behind the column (on the left in the image) and APT specimens are loaded classically in the goniometer, using home designed holders. All imaging conditions available with the microscope can be applied to characterize APT specimens. Here, an illustration is given with the automated crystal orientation mapping method. A nearly equiatomic Fe-Cr alloy with an ultrafine grain structure has been submitted to a heat treatment leading to spinodal decomposition. The visualization of grain boundaries in the APT specimen allows to localize unambiguously the location of APT analysis in the specimen.

Conclusion
This new instrument, combining APT with (S)TEM, opens up new prospects for unambiguously correlating the characterization of structural defects (such as grain boundaries, precipitates or

dislocations) identified in TEM with the chemical characterization, atom by atom, accessible in tomographic atom probes.

Opening the third dimension to your SEM with integrated fs-laser

Olena Vertsanova[1,2], Dr. Sabine Lenz[1], Martina Heller[1], Sebastian Krauss[1]
[1]Carl Zeiss Microscopy GmbH, Oberkochen, Germany, [2]National Technical University of Ukraine "KPI", Kyiv, Ukraine

Poster Group 1

Background
Scientists and engineers in materials research laboratories performing sample preparation using focused ion beam (FIB) or plasma focused ion beam (PFIB) instruments face challenges in accessing deeply buried structural features and preparing large cross-sections and trenches at micro- and mesoscale sizes. Such preparation by FIB or PFIB is time-consuming and ineffective, as it occupies an expensive microscope that could be used for more efficient processes: high-quality imaging, high-precision analysis, and sample preparation for atomic-resolution imaging. There is a need for an effective solution for the rapid preparation of site-specific micro- and mesoscale samples.
Methods
In response to these challenges, the authors present a laser scanning electron microscope (LaserSEM) as a new Zeiss solution for fast and cost-efficient high-quality site-specific sample preparation. The Zeiss LaserSEM is a field-emission scanning electron microscope (FE-SEM) with an integrated fs-laser for large 3D volume sample fabrication. This solution enables to achieve a fast site-specific preparation from the meso- to the microscale. The Zeiss LaserSEM accelerates workflows such as 3D tomography on huge sections, preparation of arrays of pillars for micromechanical testing, or even multi-modal workflows e.g. correlative experiments between X-ray microscope (XRM) and scanning electron microscope (SEM).
Results
The examples of rapid access to undersurface features by fs-laser and Cut2ROI Workflow with the ability to identify, access, prepare, and analyze deeply buried sites with precise navigational guidance using the correlation between X-ray and electron microscopes from ZEISS are presented. The fs-laser processing recipes for different materials and their application for a large cross-sectioning with further energy dispersive spectroscopy (EDS) and electron back scatter diffraction (EBSD) analysis, as well as pillar preparation for nanoindentation, compression tests, and nanoCT, are presented.
Conclusion
Integration of fs-laser into SEM allows rapid access to deeply buried structures and fast large-volume material removal and achieves high resolution and contrast imaging with the benefits of Zeiss Gemini optics. ZEISS LaserSEM is a site-specific cross-section and micro/mesoscale fabrication solution that rapidly prepares samples by accurately removing millimeter volumes of material using integrated FE-SEM imaging to achieve accuracy.

Unique in-situ characterization workflow of Cathode Components using AFM-in-SEM

Veronika Hegrova[1], Mr. Radek Dao[1], Dr. Vojtech Schanilec[1], Dr. Jan Neuman[1]
[1]NenoVision s. r. o., Brno, Czech Republic

PS-04 (3), Plenary, august 27, 2024, 10:30 - 12:30

Background incl. aims
As the demand for efficient and sustainable energy storage solutions grows, a lot of effort is dedicated to comprehending the battery components' functionalities. Not only exploring new configurations but also new materials are essential for improved efficiency, safety, lifetime, etc. of the new-generation lithium-ion batteries [1]. However, such materials require precise sample surface preparation and handling to avoid unwanted reactions or surface changes which then influence understanding of the battery component features.
Methods
In this work, we focus on the in-situ study of Cathode Active Materials (CAM) and present a unique measurement workflow that preserves the sample surface from oxidation without compromising sample preparation quality, moreover, enabling valuable insights into chemical and electrical properties. The CAM tape samples are prepared in a glovebox on a proper holder, cross-sectioned using Broad Ion Beam (BIB) polishing, and further moved to the Atomic Force Microscope in a Scanning Electron Microscope (AFM-in-SEM) for electrical and chemical characterization. The sample transfers between all instruments are realized using a safe sample transfer system under a controlled environment, so the sample is never exposed to air or humidity, and thus, the surface remains clean and preserved from chemical reactions.
Results
With such a workflow, we studied Nickel-Cobalt-Manganese (NCM) tape with solid electrolyte, see Fig. 1. We determined the electronic conductivity using Conductive AFM (C-AFM) and distinguished the individual elements using Energy Dispersive X-ray Spectroscopy (EDS), all under in-situ conditions. We see that the NCM grains are well conductive, while the solid electrolyte remains non-conductive, which is correct, as the solid electrolyte only has an ionic conductivity (the dark part of Fig. 1c). The most conductive seems to be the secondary particles interface (the brightest part of Fig 1c), which perfectly correlates to the carbon additive observed in EDS map (Fig. 1a). Such precision would be unlikely possible or very challenging without the in-situ analysis.
Similarly, we observed a CAM tape with different grains, Nickel-Cobalt-Aluminum (NCA) and NCM, in a liquid electrolyte. The connection of the EDS map with electronic C-AFM shows that the conductivity of the grains differs 1000 times. From understanding such grains and their conductivity, the difference should be much lower. As we see in the SEM image, the NCM grain had probably been delaminated from the collector, and the conductive connection with the NCM particle was established via the inter-particle interface through the NCA particle.
Conclusion
These results emphasize the need for advanced measurement workflow and instrumentation, which could greatly help in understanding the cycling effects, durability, or lifetime of both primary and secondary particles of battery components. The above-mentioned characterization workflow is convenient, time-efficient, and suitable for a proper understanding of failure analyses and quality control of the battery components. Our findings were obtained using AFM LiteScope, which is

compact enough to be used in SEM, in this case, Helios 5 Hydra DualBeam, CleanMill for fine polishing, and CleanConnect for sample transfer [2].

IM-06 (1), Lecture Theater 1, august 29, 2024, 14:00 - 16:00

Background incl. aims
Electron diffraction is a reliable tool to obtain information about the crystalline structure of nanoscale materials. With the recent emergence of more sensitive detector technology (Direct electron detectors e.g., Timepix and Medipix) the requirement for the dose applied to the sample in experiment drastically decreases.
Diffraction requires a far simpler setup as compared to conventional transmission electron microscopy as the diffraction pattern can be obtained without any lenses. This lends itself ideally to an implementation in a conventional SEM tool having several advantages such as providing more space for sample stimuli and manipulation, lower cost, and much smaller footprint. Typically, the acceleration voltage in SEM is lower compared to TEM. However, in the past years the tendency for particles' size decrease can be observed and SEM could become an attractive alternative to TEM for such materials.

Rather than taking a single diffraction pattern, the combination of a SEM tool and a fast direct electron detector allow for the efficient acquisition of 4DSTEM diffraction data, having a diffraction pattern for each probe position in a STEM scan.

There are however a few challenges:
- A lower acceleration voltage compared to TEM leads to a decrease of maximum sample thickness that can be used.
- The field of view in a SEM is much larger than in TEM. On the one hand, this is advantageous to gather statistical information on a much higher number of particles. On the other hand, a large part of this field of view is often empty resulting in long recording times with large portions of the data being empty.
- Distinguishing diffraction reflexes from the background can become challenging at the reduced acceleration voltage. This reduces the intensity of the reflections and results in poor averaged diffraction patterns which are dominated by the background signal.

To negotiate these issues new methods for data acquisition and processing should be developed. In the current work we aim to push the limit of transmission electron diffraction in SEM, mitigate beam damage and sample contamination, to make SEM a versatile tool for a high-resolution electron diffraction structure investigation.

Methods
Experiments made on a Tescan Mira FEG SEM. Diffraction data collected via an Advacam AdvaPix. Sample manipulated by custom stage of 3 Xeryon linear piezo motors in XYZ configuration mounted on rotation stage for tomography. Data processing is done in Hyperspy, controls are made with Python, image denoising is achieved with a convolutional neural network, Edge detection is realized with OpenCV.

Results
To reduce the acquisition time and avoid empty areas in the 4DSTEM dataset we use a fast overview scan from which we detect all particles positions and shapes with computer vision. In a second step we determine a scan pattern to visit only those areas which likely to give diffraction patterns. We call this approach ROI 4DSTEM: each detected particle is marked with a bounding box. We then use the assumption that particles or agglomerated particle sets tend to be much thinner on their outer boundaries as compared to their centers. These boundaries are therefore the ideal positions to get good quality diffraction data from if the assumption holds that the core of the particles is the same crystal structure as its perimeter area. We call this method Edge Detected 4DSTEM. By utilizing image denoising via a modern convolutional neural network and edge detection algorithms we were able to create with high precision a mask of scan positions that is later used to position the incident beam only at those areas that most likely will lead to good quality diffraction patterns.
This approach allows us to perform 4DSTEM in SEM in a much more effective manner. Indeed, for a standard 4DSTEM raster scan of 1024x1024 scan positions we would get 1,048,576 diffraction patterns, or approximately 182 GB of data to store and 18 minutes to collect all this data at 1 ms exposure time. In our ED4DSTEM method, we only collect 23,000 positions, resulting in 4 GB of data and 23 seconds of total recording time for the same 1ms exposure time. This is almost 50 times faster/more efficient as compared to conventional raster scanning resulting in a significant reduction of beam damage and contamination on top of the benefit of pre-filtered diffraction data of much higher average quality.
By processing each individual diffraction pattern and storing only the peak positions and their intensities we can obtain a massive data reduction that considerably simplifies the following data analysis steps. This reduced dataset can then be used for any kind of diffraction analysis. In our case we are collecting “virtual” ring patterns as a radially integrated histogram of the scattering angle of all observed peaks, weighted by their intensity. This method has the advantage of suppressing the background in the diffraction pattern that originated from substrate/noise/amorphous content in the sample that otherwise would dramatically deteriorate the quality of a position averaged diffraction pattern. An added benefit is the sub-pixel position accuracy that can compensate for beam convergence and pixel size effect.

Conclusion
In this work we present methods that allow for more effective 4DSTEM diffraction data acquisition on dispersed crystalline nanoparticles at low acceleration voltages as well as methods for more reliable data processing. Our method, compared to conventional 4DSTEM raster scan, drastically decreases the total 4DSTEM acquisition time, beam damage and contamination while providing a dramatic data reduction in the process that could significantly simplify follow the data analysis. These approaches are also amenable to TEM and could be especially useful in case of beam-sensitive objects.

Poster Group 2

Background: The successful synthesis/exfoliation of Transition Metal Dichalcogenides (TMDs) covered the need for 2D materials with an energy bandgap, which is essential for transistor applications. PtSe2 belongs to Noble-Metal Dichalcogenides, which is a subcategory of TMDs, consisting of metals from group 10 of the periodic table. It exhibits layer-dependent electronic properties, allowing it to be employed either as a semiconductor or semimetal. PtSe2 has a broad range of applications in sensing, optoelectronics, and photonics [1], while properties can be tuned through defect engineering. The occurrence of magnetism in PtSe2 has been attributed to the presence of point defects [2] while stacking sequences different than the 1T, can also enhance its performance as a piezoresistive sensor [3]. However, it is still unknown which defects in ultra-thin PtSe2 layers are caused by ultrasonication, during liquid-phase exfoliation, and how they affect the properties of the system.
Methods: All samples were exfoliated using the LPE method including eco-friendly solvents. The structural characterization of exfoliated samples was performed using the FEI Titan 80 – 300kV FEG S/TEM operated at 300 kV and the Nion UltraSTEM operated at 60 kV. Electronic properties of defected PtSe2 were calculated using FHI-aims all-electron code, while geometries were optimized using FHI-vibes. Multislice STEM imaging simulations were accomplished with abTEM code [4].
Results: Selected area electron diffraction testified the 1T structure of PtSe2, while bright-field TEM and HRTEM imaging confirmed the exfoliation into thin flakes with an average diameter higher than 600 nm. STEM-EDX mapping confirmed the presence of all involved elements in exfoliated samples. Low-voltage Z-contrast imaging was chosen to minimize the generation of defects due to beam irradiation effects. Multiple type point defects, including vacancies and antisites, as long moiré patterns, have been observed. The presence of these configurations was validated by comparing experimental with simulated STEM images, using the multislice method. The symmetry breaking due to the coupling of multiple point defects results in modified band structures and properties.
Conclusions: In this work, PtSe2 was exfoliated with liquid-phase exfoliation, and different point defects and moiré patterns were observed with low-voltage aberration-corrected STEM imaging. These different structural configurations were testified with multislice STEM imaging calculations. The effect of these structural configurations on electronic properties was estimated with ab initio calculations.

Background:
The antidiuretic hormone arginine-vasopressin (AVP) binds to the kidney V2 receptor (V2R) triggering Gs protein coupling and thereby activating adenylyl cyclase. First, the AVP-V2R-Gs signaling complex regulates body water balance and solute transport in mammals, and exhibits physiological effects throughout the body. In addition, arrestins also interact with this G protein-coupled receptor (GPCR) to stop G protein activation and to initiate other key signaling pathways.
Dysfunctions in this GPCR lead to clinical disorders, ranging from dysregulation of water balance such as the syndrome of inappropriate antidiuretic hormone secretion (SIADH, associated to many forms of cancer), congestive heart failure, hepatic cirrhosis, to urine disorders (incontinence, nocturia). Moreover, V2R loss-of-function or constitutively active mutations lead to two rare genetic diseases: (a) the congenital Nephrogenic Diabetes Insipidus (cNDI) characterized by excessive urine voiding, and (b) the nephrogenic syndrome of inappropriate antidiuresis (NSIAD) characterized by excessive water loading and hyponatremia. Unfortunately, despite the global prevalence of kidney-related diseases, there is currently no safe prescribed drug on the market for V2R-related disorders. The nonpeptide antagonist Tolvaptan approved for treating hyponatremia (SAMSCA®) and recently for polycystic kidney disease (PKD, the most frequent Mendelian inherited disorder affecting million people worldwide), has hepatotoxic effects. Discovery of therapeutic compounds based on structural information may have a direct impact on millions of citizens. To that purpose, determining both the active and inactive conformations of the V2R is crucial for a comprehensive understanding of the complete conformational changes responsible for the receptor activation or inhibition. Defining the molecular mechanisms occurring in the core of the V2R during these changes is essential for a complete understanding of its function, and to ultimately propose innovative drugs based on rational and structural data.

Methods:
By combining biochemistry and structural biology, we have successfully purified the V2R in complex with either Gs protein or βarrestin1, and structurally characterized the complexes using cryo-EM. Determining structures of the inactive states remains a challenging endeavor due to intricate biochemistry, their dynamic nature, their small size and sophisticated activation mechanism. Given this, the V2R has been modified by introducing a BRIL (cytochrome b562 RIL, 15 kDa) module in the third intracellular loop (ICL3) of the receptor. It is a promising strategy, as a Fab anti-BRIL and an anti-Fab nanobody have been designed to significantly increase the size of the receptor for cryo-EM (~100 kDa).

Results:

We have recently reported the cryo–electron microscopy (cryo-EM) active structures of the wild-type AVP V2R in complex with either Gs protein and βarrestin1. First, the cryo-EM characterization of the AVP-V2R-Gs allowed us to describe three structures, mostly based on the positioning of the Gs relative to the receptor. Those structures reveal an original receptor-Gs interface in which the Gαs subunit penetrates deep into the active V2R. The structures help to explain how V2R R137H or R137L/C variants can lead to cNDI and NSIAD. Then, the AVP-V2R-βarrestin1 structure reveals an atypical position of βarrestin1 compared to previously described GPCR-arrestin assemblies, associated with an original V2R/βarrestin1 interface involving all receptor intracellular loops. Phosphorylated sites of the V2R carboxyl terminus are clearly identified and interact extensively with the βarrestin1 N-lobe, in agreement with structural data obtained with chimeric or synthetic systems. Finally, in the core conformation, the βarrestin1 finger loop inserts into the intracellular cavity of V2R and overlaps the same binding space than the Gs α5 helix, explaining the desensitization mechanism of the V2R.

We are actually characterizing the V2R into its inactive state, using different types of antagonists. They fully antagonize cAMP signal, arrestin recruitment and MAP kinase phosphorylation associated to V2R activation. Preliminary cryo-EM data demonstrate the potential of the V2R-Bril construction to reach high resolution for the inactive state of the receptor. Resolving the cryo-EM conformation of the antagonist-V2R complex will constitutes the first characterization of an inactive structure of the V2R.

Conclusion:
Elucidating high-resolution structure of different states of the receptor using cryo-electron microscopy will allow to apply structure-based drug design to discover effective innovative drug compounds using computational approaches. In addition to bring those receptors to drug design initiatives, our data will provide new insights into GPCR's function.

Poster Group 1

Background incl. aims
In-situ SEM can help with understanding and optimization of processes forming (nano-)materials usable in electronic devices and energy storage systems. The high-temperature synthesis of these materials often happens in reactive, explosive, or harmful environments.
This study aimed to prove the functionality of the MicroReactor device for in situ SEM imaging during experiments requiring reactive gases (such as pure hydrogen or hydrogen sulfide) that result in the synthesis of the currently used and possible future battery materials.

Methods
MicroReactor device [1] equipped with a MEMS heating & biasing chip [2] was used in Helios G4 UX and Scios DualBeam systems. The MicroReactor's low-volume reaction chamber, coupled with a retractable lid enabling work with reactive gases during SEM operation and open access for sample preparation by FIB, assures improved process cleanliness and safety compared to an environmental SEM. In-lens detectors of the SEM column as well as STEM or 4D STEM detectors placed below the transparent MEMS chip can monitor changes in the processed sample. Real-time gas analysis of reaction products is possible on the outlet line connected to the reaction volume. After gas-assisted processing, EDS and EBSD analyses can follow while the sample remains heated up to 1200°C. In the latest design, the MicroReactor sample holder can be transferred in argon between a glove box and a FIB-SEM chamber.

Results
Three novel applications of MicroReactor will be presented.
1) The capacity and lifetime of NMC cathode in Li-ion battery depend on the parameters of the high-temperature lithiation process. The MicroReactor can be used to follow morphological changes of the NMC particles which indicate the state of lithiation. An example of a possible way of lithiation process, that uses LiOH as the source material, is shown in the graphics. A pure oxygen environment was selected in the MicroReactor to remove the hydrogen from the final cathode material.
2) The growth of tungsten suboxide W18O49 nanowhiskers from WO3-SiO2 nanofibers was studied in the MicroReactor [1]. Reduction of the WO3 in nanofibers was possible at 800°C in a hydrogen environment (100 Pa). The tunability of redox properties, thermal stability, and large surface area make tungsten suboxides promising materials for applications in energy storage systems.
3) Tungsten disulfide is a 2D material with unique properties applicable in many fields including electronics, catalysis, and energy storage. A modified pumping system of the Scios DualBeam equipped with MicroReactor enabled the injection of hydrogen sulfide & hydrogen mixture which was essential for the successful sulfidation of a sample containing W18O49 nanowires. Using a combined in-situ SEM and ex-situ TEM analysis, it was possible to explain the mechanism of WS2 synthesis from tungsten suboxides for the very first time [3].

Conclusion

The three presented examples demonstrate novel applications of the MicroReactor in SEM. The second example proved process cleanliness sufficient for sample reduction at high temperatures. The creation of this abstract proves the possibility of safe work with dangerous gases in the third example, which at the same time demonstrates the possibility of exploring the fundamental behavior of chemical processes.
In addition to the conclusions summarized in [1] and [3], it can be stated that in situ SEM equipped with the MicroReactor is a useful complement to the more widespread TEM in-situ techniques, which can bring new insight with several benefits. SEM excels in capturing reaction kinetics at a larger scale and provides topographical information in the surface-sensitive signal of secondary electrons. The presented technique can further be combined with ex-situ TEM analysis or with ETEM, both on the same MEMS chip that is used in SEM.

Background
Liquid phase transmission electron microscopy (LPTEM) is a small field in the realm of microscopy. However, its significance appears in understanding various scientific domains. However, measuring the main driving force in many liquid-based processes, e.g., in electrochemistry, is still yet to be fully explored. Similarly, understanding the liquid itself is key in quantum mechanical models for our understanding of how liquids behave.
Electron holography (EH) has emerged as a new tool to measure both the electrostatic- and magnetic potentials of a specimen. As the electrons from the incoming electron beam undergo elastic scattering, a phase shift is presented in the exit wave [1]. In EH, the phase shift is measured by measuring against a reference wave, which has not been shifted in phase. By computing the phase shift between the two waves, the object and reference wave, the electrostatic and magnetic potential are retrieved by post-mortem analysis.
It, therefore, begs the question if it is possible to combine EH with LPTEM in order to measure those potentials, which may be used in more delicate systems in order to study liquids and liquid-based processes where the potential is the main driving force, e.g. in any electrochemical experiment. We coin the new method of Liquid Phase Transmission Electron Holography (LPTEH).
Methods
In LPTEH, we make use of two primary chips, which have previously been used in LPTEM to examine nanoscale liquid-based processes. The first type of chip used, the nanochannel chip, is a chip comprised of two bonded silicon wafers with nitride as the window material, see Figure 1(a). The thickness in the nanochannel chip is much better defined, given that the channels have a width of < 2 µm, where bulging is less compared to the clamped liquid cell with a width of > 100 µm. However, these chips have not yet been fabricated with electrodes. Thus, the nanochannel chip is primarily used via LPTEH to determine the intrinsic properties of the liquids.
The other type of chip, the clamped liquid cell, is an LPTEM cell where the liquid is squeezed between two electron transparent windows, see Figure 1(b). The thickness of the liquid is defined by how thin a liquid can be squeezed by squeezing on the surrounding O-ring. Additionally, we have in our clamped liquid cell fabricated Au electrodes, where we start to examine how to use those chips for any electrochemical experiments. Lastly, EH itself is done using a TEM. There are two main methods for EH, namely in-line and off-axis EH. For our experiments, we use off-axis EH, since the TEM at DTU (the FEI 80-300 kV E-TEM) has a standard ThermoFisher biprism (a quartz filament) installed in the SAD plane. We carry out experiments on a single biprism setup, where the biprism voltage determines both the interference width and the fringe spacing.
Alignment of the object and reference wave can be done in different ways for both chips. For instance, if one were to examine the liquid itself on the nanochannel chip, the reference wave is usually passed through the bonded nitride between the channels, as that defines a common 0 rad phase shift. If features in the liquid are instead studied, the reference wave can be passed through the liquid, thus only the phase shift elastic scattering with the feature is measured.
Results

We show our latest results of both systems and some of the features studied with LPTEH. First and foremost, we extend an earlier paper on the study of the mean inner potential (MIP) of water [2], where our updated results show how the MIP can be understood as a refractive index for high energy electrons by studying the change in MIP of glycerol:water mixture, see Figure 1(c). By increasing the volume fraction (f_g) of glycerol, it can be seen that the MIP of the mixture increases linearly shown by the dashed black line in Figure 1(c). This linear increase with solute concentration can be thought of as an analogy to how the optical refractive index increases linearly with solute concentration, which was also how the MIP was first described by H. Bethe [3]. We compare our experimental results to a first-order approximation of the MIP, known as the independent atom model, shown as the dashed red line in Figure 1(c), and compare our results of pure MQ water with [2] shown as the blue data point. Evidently, it can be seen that the MIP is the refractive index of high-energy electrons, and it behaves similarly to the optical refractive index.
In our second example, we show how LPTEH can be used to measure the potential from the solid-liquid interface, see Figure 1(d). This study shows how LPTEH can be used to measure the potential of the electric double layer, which is key in any electrochemical process. Its potential profile indicates that of a screened potential, which is understood as the screening of free ions in the liquid. Such a measurement of the potential is the first of its kind, as most techniques use an almost ideal non-polarizable reference electrode. However, the e-beam used for EH/LPTEH is ideally non-polarizable, as it does not create its own double layer contrary to any solid reference electrode. It could, therefore, be speculated that the e-beam can be used in the future as an ideal reference electrode and be able to measure the driving force in any electrochemical experiment.
Conclusion
In summary, we have shown two studies of how LPTEH can be used to measure the driving force and intrinsic properties of a liquid. By combining two TEM-based methods, LPTEM and EH, we have shown how we may start to use LPTEH as a new tool to understand liquids in a deeper understanding. We note that this is the first of its kind, and thus, there is still much to improve in terms of spatial resolution to better capture the innermost layer of the double layer, where our results only provide evidence of the outermost layers of the double layer.

Poster Group 1

Energy electron loss spectroscopy is already an established technique to study structure and property relationship required to optimize materials and make break-through inventions in material science. So far EELS lacks performance at energy losses higher than 2 keV to obtain bonding or coordination state information via ELNES or EXELFS with high lateral resolution [1]. We used a new optical setup designed to optimize the coupling between spectrometer and post-specimen optics for high energy resolution and high collection efficiency. The new optical setup allows to minimize the acquisition time (minutes) and the beam current to avoid sample damage or drift artifacts and to achieve results beyond the earlier attempts reported in literature [2].
The real application benefit in EELS is its spatial resolution which is much better than the micron resolution that XAS can achieve. A challenge lays in analysis of elements in low concentration due to the signal strength. For this reason we have made a comparison between XAS and EELS data from a sub-micron size precipitate on the Zr_L23 edge in high-strength, translucent glass-ceramics in the system MgO-ZnO-Al2O3-SiO2-ZrO2 with only 5.8% Zirconia in the compound [3]. The comparison of ELNES with XANES reference data clearly reveals that the coordination is CN=8.
For a more quantitative comparison the setup was used to acquire Cu_K edge at 8.98 keV energy loss from metallic Cu, CuO and Cu2O. The EELS data is benchmarked against XAS data in XANES and EXELFS and relevant information is extracted from the EELS data using similar analysis as done for XAS data. It is noteworthy to mention that the results show an excellent match of EXELFS and EXAFS and the EELS data allows extracting the bond length with very good accuracy as it will be shown in this work.
In order to further assess the optimization of the entire EELS optics including the S/TEM column we have acquired a series of K-edges at extreme energy loses namely the Mo K-edge at 20 keV, Ag K-edge at 25.5 keV and Sb K-edge at 30.5 keV as presented in figure 1 (from left to right: Cu K-edge, Mo K-edge and Ag K-edge) and for some of the materials the bond length has been calculated from the EELS data.
With this work we will also discuss the limitations of the current technology and how they are mitigated by the deep integration of the filter in the optics on the new platform.
The integrated approach optimizing the entire EELS optics including the S/TEM column enables this increase in performance. The examples presented show the power of correlative studies involving X-ray absorption spectroscopy (XAS) and high loss EELS, which opens new applications to combine the advantages of both techniques.

Structure Prediction using Data Derived Potentials and EELS

Thomas Ginnis[1], Professor Rebecca J Nicholls[1], Professor David Armstrong[1]
[1]Department of Materials, University of Oxford, Oxford, United Kingdom

IM-05 (1), Lecture Theater 3, august 26, 2024, 10:30 - 12:30

Background

(Scanning) Transmission Electron Microscopy ((S)TEM) coupled with Electron Energy Loss Spectroscopy (EELS) is a powerful and information rich technique capable of providing information about composition and local bonding environments at a high spatial resolution. However, the Energy Loss Near Edge Structure (ELNES) of core-loss EELS peaks can be difficult to interpret due to the large number of factors which can influence the ELNES shape. Traditionally, spectra collected from known standards have been used to interpret ELNES, or spectra have been simulated from structures obtained from databases such as the Materials Project or the Inorganic Crystal Structure Database. This work presents a workflow for using Ab-Initio Random Structure Searching (AIRSS) accelerated by Ephemeral Data Derived Potentials (EDDP) to predict the structures of compounds after measuring their composition using quantitative EELS, then using CASTEP and OPTADOS to predict the ELNES of these structures. The workflow has been tested on silicised boron nitride, a system important in high temperature ceramic matrix composites.

Methods

TEM lamella were prepared from single crystal SiC and silicised BN. A TEM sample of commercially pure BN was obtained by dispersing the BN nanopowder on a carbon grid. The TEM samples were analysed using STEM-EELS, and elemental maps, thickness information, and ELNES datasets were obtained.

These EELS datasets were fitted with the model fitting functionality of Hyperspy, and these models were used to calculate the compostitions of the samples.

After calculating the composition of the silicised BN sample, a unit cell of this composition was generated containing multiple formula units. The cell was then used to train a data derived potential, capable of calculating the energy of an arrangement of atoms given their coordinates. This was performed with the EDDP code, which generates random sensible structures and calculates their energy using the plane wave pseudopotential Density Functional Theory (DFT) code CASTEP with the Regularised Strongly Constrained and Appropriately Normed (rSCAN) functional and the Many Body Dispersion (MBD) semi-empirical dispersion correction to account for long range van der Waals forces. These atomic coordinates and energies are used as the training data for an ensemble neural network.

The initial potential learned by the system will have a large error, but is sufficiently robust enough to allow for structure searching, by generating a random sensible structure and relaxing it to a local minimum using the learned potential. DFT is then used to calculate the actual energies of the minima of this initial structure search, and expand the training data for the learned potential. The network is retrained on the expanded training dataset.

This process is repeated 5 times until a robust and accurate potential is formed. This potential can then be used for rapid random structure searching and can predict low energy structures of the unit cell defined by the measured composition.

The lowest energy structures are then relaxed further using DFT to ensure they are at true energy minima, and the ELNES spectra for each of the atomic environments present are calculated using CASTEP and OPTADOS.

These calculated spectra can be used as reference spectra in a library and can be compared directly with ELNES measured in STEM-EELS experiments.

Results

The validity of the model fitting functionality in Hyperspy for determining the composition of silicised BN was tested using the pure BN nanopowder and semiconductor grade SiC, and the method could predict the compositions of these known compounds, proving that the quantification method is suitable for systems containing Si, C, B and N.

Initial EDDP calculations involved the Si-B-N system. A unit cell containing 3 Si, 6 N and 5 N atoms was created, and this composition was chosen based on literature values of the typical composition of silicised BN. An ensemble neural network containing a single layer with 5 nodes was produced, and this resulted in a potential with an error of less than 30 meV / atom on the testing set.

This data derived potential was used for a random structure search of over 10,000 structures. The lowest energy structures were selected, and a stricter geometry relaxation was performed using DFT. The EELS spectra for these low energy structures were calculated with CASTEP and OPTADOS before being compared with experimental spectra from silicised boron nitride. This allowed for information about the local bonding environment to be understood.

Conclusions

The EDDP method has enabled rapid random structure searching of systems which were previously too large to search efficiently. This has opened up a workflow in which EELS can be used on a wider range of materials, including those which do not have high quality reference standards or even known crystal structures in large databases.

The usefulness of this workflow was demonstrated on silicised BN, and further work could use a similar workflow to understand how the composition and ELNES of these materials changes as a result of environmental degradation.

Poster Group 2

Four-dimensional scanning transmission electron microscopy (4D-STEM) can provide quantitative information about electric fields in materials and it is currently a technique of choice for such measurements. However, mapping electric fields over large (micrometers) field of view with a very high sensitivity and a nanometer spatial resolution remains challenging [1]. Herein, we perform a systematic study to evaluate the expected achievable precision of 4D-STEM measurements for electric field mapping in vacuum.
All experiments were performed on a Thermo Fisher Scientific Titan Themis TEM operated at 300 kV in micro-probe configuration and equipped with a MerlinEM detector. First, the effect of microscope parameters was investigated by acquiring 4D-STEM maps in vacuum while varying one parameter at a time such as convergence semi-angle, electron beam current, dwell time or camera length. To assess the accuracy of the electric field mapping, a coplanar capacitor was fabricated by focused-ion beam (FIB) deposition of Pt on a MEMS biasing chip (DensSolutions). The center of mass (COM) method was used to analyze the shift of the transmitted beam, which was achieved by subtracting the COM map obtained at an applied voltage (object map) from a COM map in free field conditions (reference map) [2]. The reconstructed electric field was then compared with the results of finite element method (FEM) simulations using COMSOL [3].
The electric field sensitivity was evaluated in terms of measurement error. The results show that reducing the convergence semi-angle increases linearly the sensitivity but has a negative effect on the spatial resolution. Electron beam current and dwell time are also shown to have a direct effect on the field sensitivity, as directly controlling the electron dose. In practice, low electron dose values mean low sensitivity, which follow the root square behavior of the Poisson noise. Finally, the camera length study shows that this parameter has no influence on the sensitivity except for extremely small values when it strongly deteriorates. Overall, the experimental trends are in good agreement with previous theoretical studies [4]. The microscope parameters that optimize the measurement, including a convergence semi-angle of 370 µrad, dwell time of 2 ms, electron beam current of 150 pA and camera length of 1.45 m, were then used to quantify the stray electric field of the capacitor induced by an applied difference of potential between the plates. The integral of the in-plane component of the stray electric field over the electron path was directly compared with a FEM model where the simulated electric field was integrated along the z direction, assumed to be the direction of electron propagation. This comparison revealed good agreement for applied voltages in the range of 1 to 10 V, corresponding to a maximal projected field in the capacitor gap of 2 to 25 V, respectively. Finally, the electric field reconstruction was repeated using the template matching (TM) method and the results showed that proper choice of template is essential for comparable trends.
In conclusion, this study highlights the effects of microscope parameters on the sensitivity of large field of view electric field measurements using 4D-STEM and provides guidelines for optimized measurements. The full quantification of the electric stray field induced by an applied external potential is demonstrated as an example.

Poster Group 1

Background
Electrochemical devices such as fuel cells and electrolysers enable chemical and energy transformations that are required to help achieve net-zero targets by 2050. One of the emerging technologies is electrochemical reduction of CO2 into value-added products, such as carbon monoxide, formic acid and ethylene. [1] The best performing cathode catalyst for producing ethylene and other C2+ products in a CO2 electrolyser is oxide-derived copper (OD-Cu), which is metallic coper formed in situ via reduction of a copper oxide-based electrode in the electrolyser. The activity of OD-Cu tends to be significantly higher than that of similar Cu catalysts that have been reduced ex situ prior to being incorporated into the electrolyser, which suggests that additional or superior active sites are generated during the in situ electrochemical reduction [2]. In addition, the catalyst can experience significant structural changes under CO2 electroreduction conditions [3]. Obtaining structure-performance relationships of copper requires in situ characterization, which is due to the surface oxidation and possible restructuring the metal experiences when exposed to open circuit potential and air during disassembly of the electrochemical cell. In situ characterisation imaging techniques such as XAS and XRF are therefore a crucial step to capture the active catalyst formation and the morphology dynamics under electrochemical conditions. These techniques suffer from lower spatial resolution, which limits the level of understanding of the underlaying dynamics for reactions involving gases or liquids. This motivated our investigation of the hypothesis that specific conditions of thermal reduction experiments can led to the Cu structures formed under electrochemical conditions. In this way, a higher spatially-resolved analysis could be done by extrapolation from gas-phase investigation.
Methods
In this work we present in-situ TEM gas phase thermal reduction experiments of CuO samples and correlate them with in-situ liquid phase electrochemical reduction of CuO samples carried out on the i14 nanoprobe beamline (Diamond Light Source). Synchrotron-based spectroscopy techniques, such as X-ray absorption spectroscopy (XAS) and X-ray fluorescence spectroscopy (XRF) are very powerful methods to study the chemical nature of the catalyst under relevant conditions [4]. Combining the i14 nanoprobe beamline(down to 50 nm resolution) with aberration corrected electron microscopy (Å resolution) allows to use spatially resolved XRF imaging to study morphology and dynamics in a liquid biasing environment and link it to gas-phase experiments on the nanoscale.

Results/Conclusion
We will show the benefit of combining these techniques to reveal the effect of the thermal reduction on the CuO particles (morphology / oxidation state) through a combination of in-situ STEM imaging and EELS versus the electrochemical reduction as revealed by the in-situ liquid cell i14 XRF/XANES experiment (Figure 1). We will also address the challenges with liquid biasing experiments such as beam-induced damage, especially to the ionomer that is commonly present in catalyst layers (e.g. Nafion), and challenges involved with sample preparation.

Epitaxially-assisted Sn Crystal Phase Selectivity on Hybrid Superconductor-Semiconductor Quantum Nanowires

Sara Martí-Sánchez[1], Dr Sabbir A. Khan[2], Prof Peter Krogstrup[3], Prof Jordi Arbiol[4]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Bellaterra, Spain, [2]Danish Fundamental Metrology, Copenhaguen, Denmark, [3]NNF Quantum Computing Programme, Niels Bohr Institute, University of Copenhagen, Copenhaguen, Denmark, [4]ICREA, Barcelona, Spain
PS-03 (1), Lecture Theater 2, august 29, 2024, 14:00 - 16:00

Background incl. aims
Hybrid systems of semiconductors connected to metals/superconductors provide interesting platforms to explore exotic topological properties for topological quantum computing purposes. In particular, Sn is a promising material as it can present two main structural phases when deposited on III-V semiconductor nanowires (NWs): semimetallic α-Sn (cubic) and metallic β-Sn (tetragonal) which also presents superconductivity below 3.7 K. In addition, α-Sn can turn into a topological insulator under strain [1] and β-Sn has the potential to turn into a topological superconductor when hybridized with a strong spin-orbit coupling 1D semiconductor, as In-V (V=As/Sb) nanowires (NWs) [2]. However, few studies focus on the deposition of Sn in NWs, and coexistence of α-Sn and β-Sn on InSb NWs has been reported. Therefore, achieving Sn phase selectivity on In-V NWs remains challenging.

Methods
In this work, we have deposited Sn on different In-V compounds including zincblende (ZB) InSb and InAsSb and wurtzite (WZ) InAs and we explore the role of epitaxial relationships between Sn and the NW in crystal phase selectivity based on Atomically Resolved Scanning Transmission Electron Microscopy.

Results
After the optimization of different growth conditions, our studies reveal that the main parameter determining Sn phase is the crystal lattice of the NW, which acts as a template assisting the Sn crystal arrangement. InSb acts as a template for the growth of a monophase α-Sn shell that evolves to β-Sn rich shell with increasing β-Sn density when increasing layer thickness, and so, the accumulated strain. In a second step, poorly lattice matched NW templates of InAs WZ were employed for Sn growth, where selective β-Sn could be grown by enhancing interface energy between α-Sn and the NW. At the same time, our structural characterization is complemented with device fabrication and electrical measurements, where superconductivity yield in the measured NWs is in agreement with the atomic structure of Sn.

Conclusions
As a summary, our studies reveal that Sn phase control is mostly driven by the structural arrangement of the nanowires and we are able to selectively tune the Sn phase formation by employing the desired NW template. Therefore, this work provides a key to control Sn phases on hybrid NWs to permit the tuning of the topological properties by unveiling the insights of Sn growth.

Poster Group 2

Viruses in the PRD1/Adenovirus (AdV) -like lineage infect bacteria, archaea and eukaryotic organisms and build their capsids with proteins with beta-jelly rolls orthogonal to the capsid surface (1). It has been suggested that Polintons (dsDNA transposons) are members of this lineage, because they encode genes very similar to viral proteins involved in replication, assembly, maturation, and possible structural proteins with jelly roll fold. These observations prompted the hypothesis that Polintons may have evolved from a PRD1-like ancestor (2). Subsequent evolution would have resulted in the "polintovirus" elements splitting into two different ways of life: the transposable, capsid-less integrating elements, and the bona fide viruses. Marine metagenome analyses have revealed a group of putative polinton-like viruses (PLVs) in eukaryotes. PLV genomes contain genes for single and double jelly roll proteins and a packaging ATPase, but lack the protease and integrase genes present in the polintons (3). Therefore, PLVs could represent a minimal version of the PRD1/AdV-like lineage in eukaryotic hosts. The study of this kind of virus could reveal the adaptations necessary for the jump from a bacterial to eukaryotic host. The first isolated PLV, TsV-N1, infects the unicellular eukaryotic algae Tetraselmis striata (4)

We have used cryo-electron microscopy to solve the structure of TsV-N1, and FIB-SEM volume electron microscopy on resin-embedded cells to analyse the structural changes induced by infection in the host. The high-resolution capsid structure (2.7 Å) corroborates the placement of TsV-N1 in the PRD1/AdV-like lineage and reveals similarities with those of bacteriophages in this lineage, although TsV-N1 infects a eukaryotic host. These similarities include: triangulation number T = 21d, size, genome arranged in concentric rings. However, the main differences with bacteriophages in this lineage are the absence of an inner membrane, the major capsid protein fold being more similar to other eukaryotic viruses, a complex cementing protein network and a high packing fraction, more similar to those of HK97-like viruses. TsV-N1 induces large changes in the host during the infection. Although this virus assembles in the nucleus, other cellular structures are modified too. Particularly striking is the disappearance of starch grains and the cell wall, suggesting that the virus hijacks energy sources for propagation. More studies must be carried out to understand how this virus reaches the nucleus. However, its similarities with AdV (no membrane, nuclear assembly) suggest that similar genome delivery mechanisms may be involved.

Correlative analytical scanning electron microscopy reveals periprosthetic tissue response to nanoparticles and wear debris

Dr Louise Hughes[1], Pedro Machado[1], Joshua Lea[1], Zhidao Xia[2]
[1]Oxford Instruments NanoAnalysis, High Wycombe, UK, [2]Swansea University, Swansea, UK

Poster Group 2

Background
One of the leading factors in aseptic loosening, osteolysis, and subsequent failure of implants used for total joint replacement is the production of wear debris and the associated reaction in periprosthetic tissue [1]. Nanoscale wear particles (0.2-0.8µm) are a critical component in the activation of macrophages and inflammatory response [2]. Particle composition, identified using electron microscopy and energy dispersive x-ray spectroscopy (EDS), can determine their site of origin [3] and is a critical factor in macrophage cytotoxicity and the activation of pro-inflammatory cytokines [4]. However, EDS can only provide part of the information required to understand the molecular interactions between patient tissue and wear debris. Organic/inorganic molecules and their interactions are not detected by EDS alone.
Methods and aims
Here we present a correlative study incorporating a fast compositional imaging method for rapid identification of regions of interest (backscattered electron x-ray, BEX, imaging) across large tissue areas, combined with higher resolution EDS and Raman spectroscopy. Samples were prepared following methods presented by Xia et al. [3] with modification for scanning electron microscope (SEM). The uncoated resin-embedded tissue samples were imaged in a Zeiss Gemini460 SEM in variable pressure mode at 10kV using a Unity BEX imaging detector combined with an Ultim Max 100 EDS detector, followed by analysis with RISE (Raman Imaging Scanning Electron). RISE imaging was conducted using a 785 nm laser, tuned to 25 mW using the TruePower module. The multimodal imaging datasets were colocalised and overlayed using the Relate software package (version 9.3.10333).
Results and conclusions
We investigated the ultrastructure, chemical and elemental properties of tissue interacting different wear particles. We observed particles of titanium accumulated into large clusters (50 to 500µm) surrounded by tissue that had distinct density difference. High density areas of the tissue were characterised by an elevated weight percentage (wt%) of calcium (Ca) and phosphorus (P) (Figure 1 BEX). RISE analysis of the same region shows spectra indicating two phosphate populations: one spectrum was characteristic of hydroxyapatite, the second was bound to tissue stained with lead citrate with the presence of lead confirmed using both Raman spectroscopy and EDS. A third spectrum peak in the carboxylate region, overlays with the low-density tissue observed by BEX (Figure 1 RISE, RISE spectrum, BEX + RISE overlay). Similar results were observed in samples containing much smaller (<0.8µm) cobalt nanoparticles.
The multimodal and correlative approach combines the speed of BEX screening with high-resolution characterisation (EDS and RISE) of tissue reactions to nanoscale wear particles. The proposed correlative workflow can generate detailed structural and molecular data for studying the effects of metal nanoparticles from implants and may provide a fast screening technique to facilitate diagnostic analysis of pathological features in the future, in particular the molecular mechanism that triggers host allergic and inflammatory response to orthopaedic implants.

Fig 1. Overlayed BEX and RISE images show 3 distinct tissue phases characterised by different electron density (BEX), chemical (RISE, RISE spectrum) and elemental compositions (BEX, BEX+RISE overlay). BEX images display Uranium (U) and Lead (Pb) in cyan, Titanium (Ti) in yellow, Calcium (Ca) in pink and Phosphorous (P) in blue, electron image in greyscale. RISE images and spectra: Hydroxyapatite in red, resin substrate in blue, metal bound Phosphate in green.

[1]Ludwig-Maximilians-Universität München, Faculty of Biology, Plant Development, Planegg-Martinsried, Germany, [2]Ludwig-Maximilians-Universität München, Faculty of Biology, Systematic Zoology, Planegg-Martinsried, Germany, [3]Ludwig-Maximilians-Universität München, Faculty of Biology, Plant Evolutionary Cell Biology, Planegg-Martinsried, Germany

LS-07 (1), Lecture Theater 4, august 28, 2024, 11:30 - 12:30

Background incl. aims
In order to survive sub-lethal heat stress, plants possess the ability to acclimate to moderately elevated temperature. They are altering their physiology in many different ways to maintain cellular homeostasis despite the change in environmental conditions. The carbohydrate metabolism is important for energy storage and biomass production and is also involved in regulation of heat acclimation response. To accurately resolve subcellular metabolic fluxes and compartment specific metabolite concentrations in the model organism Arabidopsis thaliana, it is necessary to combine ultrastructural and metabolic data.
Methods
A non-aqueous fractionation procedure to determine subcellular metabolite concentrations was combined with 3D imaging of leaf tissue by serial block-face scanning electron microscopy, which resulted in two datasets of control and heat treated samples.
Results
We were able to generate a dataset of subcellular volumes of A. thaliana leaf tissue. This allowed us to calculate effective metabolite concentrations in three compartments of the cell, namely cytosol, vacuole and chloroplasts. Applying a kinetic model of carbohydrate metabolism, subcellular fluxes were estimated which revealed metabolic heat acclimation strategies of plant metabolism and provide evidence for a tightly regulated metabolic network.
Conclusion
The combination of microscopic techniques with metabolic and photosynthetic measurements allows a more holistic interpretation of plant heat acclimation and can help preventing misinterpretation of the individual datasets.

Poster Group 1

Background
Visualizing single cell dynamics shaping complex tissues and understanding the underlying mechanisms is an overarching goal in biology. However, these processes often cross large spatiotemporal biological scales, are affected by sample-to-sample variability and are rather sensitive to light. Light-sheet microscopy is due to its high spatiotemporal resolution and low phototoxicity a method of choice for imaging of living samples. Multi-view light-sheet microscopy has been designed for imaging of large specimens by acquiring images from opposing directions using several objectives or rotating the sample. However, these techniques are limited in throughput. For multi-sample imaging, open top, inverted or single objective approaches have been developed, where the sample is supported from the bottom while allowing accessibility from the top. These microscopes can not provide imaging from opposing detection sides. We aimed at developing an open top, dual-view and dual-illumination light-sheet microscope, combining the advantages of the multi-view and open top design enabling multi-position 3D live imaging of large multicellular systems.
Methods
The presented open top, dual-view and dual-illumination light-sheet microscope uses two opposing detection objectives to image samples from two directions and two illumination objectives tilted from the horizontal. This arrangement of the four objectives creates an unobstructed linear space for a custom designed sample holder which has space for up to four interchangeable sample chambers enabling multi-positional imaging, manufactured from FEP by a thermoforming process. Water is used as immersion medium and is placed in a reservoir filling the space between the objectives. The objective area is equipped with environmental control (humidity, temperature and CO2).
Results
We demonstrate the capabilities of the light-sheet microscope by long term live imaging of murine intestinal organoids, hydra, liver organoids, gastruloids, murine salivary gland organoids and human colon cancer organoids for more than 8 days. Moreover, with the multi-chamber design we show parallelized biochemical perturbations on murine intestinal organoids. To demonstrate its potential to extract quantitative features across biological scales, we developed a custom light-sheet data processing and analysis pipeline. Single cell tracking and segmentation analysis is performed during intestinal organoid and gastruloid growth. We could reveal cell shape changes and an increased cell motility induced by a Wnt activation pulse, suggesting a partial epithelial to mesenchymal transition in gastruloids.
Conclusion
In conclusion, we developed a dual-view and dual-illumination open-top light-sheet microscope designed for long-term, multi-position imaging of diverse samples at single-cell resolution. The image quality is suitable for cell segmentation and tracking throughout the entire organoid. We achieved sample-specific and flexible mounting by utilizing a thermoforming process to produce sample

holders of various shapes. The developed light-sheet data processing pipeline serves as the starting point for the implementation of a new data analysis framework for light-sheet data.

Quantitative Analysis of Magnetic Spin Textures in Fe3-xCoxGeTe2 Compositions using 4D-STEM

Mr. Aidan Horne[1], Dr. Daniel Mayoh[1], Dr. Damien McGrouther[2], Prof. Geetha Balakrishnan[1], Dr. Peng Wang[1]
[1]Department of Physics, University of Warwick, Coventry, United Kingdom, [2]JEOL (UK) Ltd., Welwyn Garden City, United Kingdom

Poster Group 1

Magnetic spin textures are becoming increasingly important in the field of spintronics due to their potential uses in devices such as racetrack memory. The discovery of skyrmions in Fe3GeTe2 (FGT), has triggered a great interest in studying spin textures in 2D-van der Waals (2D-vdW) magnets. These textures arise from the interplay between the Dzyaloshinskii-Moriya interaction (DMI), exchange interaction and the zeeman interaction in the presence of an external magnetic field [1]. Controlling these textures can further be achieved through factors such as thickness of the material, the temperature and structural defects [2]. Recently, it has been reported that the level of substitution of the Fe within the material by Co can change the ordering temperature and thus the behaviour of the material Fe3-xCoxGeTe2 or (FCGT) [3]. Understanding how these factors affect the behaviour of the skyrmions including the size, mobility and stability is crucial, as these features will be important when considering the materials used in potential spintronic devices such as racetrack memory or in probabilistic computing applications [4].
Here we use transmission electron microscopy (TEM) as well as four-dimensional scanning transmission electron microscopy (4D-STEM) to quantify the behaviour of FCGT as the composition of the material changes. Additionally, we simulate the textures using micromagnetic simulation software mumax3 [5].
In this work we utilize Fresnel imaging in Lorentz TEM (LTEM), a technique where the objective lens of the microscope is turned off to reduce the magnetic field so that the sample is not uniformly magnetized by the magnetic lenses. The beam is then defocused to the order of 0.1 mm so that Fresnel fringes appear caused by the magnetic potential of the sample revealing the spin textures in the sample as seen in Figure 1(a-b). These images can then be reconstructed using transport-of-intensity (TIE) equations to obtain the magnetic field information of the sample, an example of which is demonstrated in Figure 1(c). Chemical vapour transport and standard focused ion beam lift-out procedure were used to prepare the sample. During TEM imaging, the samples were cooled to liquid nitrogen temperatures and then heated to the appropriate temperature desired. The residual magnetic field within the TEM was calibrated using a custom-built in-situ Hall probe holder. The composition mapping was studied using energy dispersive x-ray (EDX) methods. Additional investigations into the material's bulk magnetic properties were carried out using magnetic force microscopy (MFM).
Using the methods described we have studied a range of stoichiometries of FCGT by varying out-ofplane (OOP) magnetic fields and temperatures and have demonstrated how the domain structure and temperatures at which these domains occur vary depending on the composition of the material. We have also confirmed the level of cobalt doping in FGT using EDX methods to quantify how this doping affects the behaviour of the materials, as well as investigated whether the elements are uniformly distributed throughout the material and how this affects the spintronic behaviour. Using the techniques described and through controlling the temperature and OOP magnetic field we have investigated the spin texture the material occupies at any given phase. Micromagnetic simulations

were done to estimate the behaviour of the materials at different thicknesses to verify results as well as to improve the speed of workflow when working on time intensive processes such as MFM and LTEM where the sample has to be cooled before imaging.
We have observed magnetic spin textures in a range of compositions of FCGT, showing that the behaviour of the materials depends directly on the levels of iron and tellurium as well as on any cobalt doping. Work has begun to further quantify the behaviour of these systems more accurately using 4DSTEM methods such as centre of mass measurements (COM) and ptychography, the methodology of which is shown in Figure 1(d).
Figure 1: Experimental setup of Fresnel TEM and 4D-STEM data acquisition. (a) Schematic of Fresnel TEM set up in overfocused condition. (b) Fresel TEM image of FGT showing skyrmions. (c) Reconstruction magnetic data. Here showing TIE reconstruction but other methods such as COM or ptychography would obtain a similar result. (d) Schematic of 4D-STEM experimental configuration.

Background incl. aims
Wurtzite III-nitride semiconductors are well known for their intense spontaneous and piezoelectric polarization fields. A deeper understanding of these properties is relevant for applications in various fields such as optoelectronic or power electronic devices. Off-axis electron holography is a powerful tool to measure directly and with a nanometer resolution the total electrostatic potential in these materials. However, to be able to study the polarization fields in III-nitrides, we need to remove the contribution from mean inner potential (MIP), which corresponds to the volume average of the Coulomb potential in the specimen. In the literature, MIP is traditionally derived for bulk materials within density functional theory (DFT).1,2 Evaluating the MIP using electron holography, we noticed disparities with values from the literature. One explanation that we propose is that the calculation for bulk material does not reflect the reality of heterostructures that are used in devices, with for instance the importance of strain. We propose here a deep analysis of the MIP evaluation for III-nitrides, comparing electron holography results with DFT calculation of the MIP that include the variation of strain.

Methods
MIP was computed through ab-initio simulations performed using GPAW code with plane wave basis-set of 300 eV cutoff energy, PBE functional, and 8x8x1 k-point sampling. The calculations were performed in a slab containing 11 atomic layers terminated in nonpolar m-{10-10} facets, centered in a 6.2-nm-long vacuum region with periodic boundary conditions. The MIP was obtained by averaging the Coulomb potential in the center 7 atomic layers, to prevent surface effects. The effect of strain has been modelled considering a biaxial strain configuration for layers grown along the <0001> direction.
From the experimental point of view, we study here 4 different samples. The first structure consists in a 6-period non-polar AlN/GaN (13nm/16nm) on 60 nm of AlN deposited on a (1-100) SiC substrate. The second sample is a 10-period polar AlN/GaN (20nm/20nm) superlattice grown by plasma-assisted molecular beam epitaxy (PAMBE) on 100 nm of GaN deposited on 1-µm-thick AlN-on-sapphire templates.3 The third and fourth samples consist in 5-period GaN/InGaN multi-quantum wells (MQWs) grown on a 2 µm-thick GaN layer that is itself grown on a 220-nm thick AlN buffer layer on patterned Si(111) templates using low-pressure metal organic vapor phase epitaxy (MOVPE). In one of the samples, the MQW consists in 5 periods of In0.13Ga0.87N (2 nm)/GaN (12 nm). In the other one, the indium content in the barriers is higher, between 14 and 16%.4 These samples have been studied using off axis electron holography performed in a double corrected FEI Titan Ultimate TEM operating at 200kV. Electron holograms were recorded on a Gatan One View 4k camera. TEM specimen were prepared by in-situ lift-out focus ion beam (FIB) using a FEI Strata 400.

Results

III-nitride heterostructures are usually grown along a polar axis, resulting in strong polarisation-induced internal electric fields that contribute to the total potential measured in electron holography. Additional contributions come from dopants, which can partially screen the internal electric fields, and from the MIP. Our first experiment consist in an attemp to measure MIP in an AlN/GaN heterostructure. To avoid the presence of internal electric fields, the heterostructure was grown along a non polar axis, and we verified that the lattice was fully relaxed. We obtained a difference of MIP between GaN and AlN of 1.53 V which is very different from the generally accepted 1.01 V, calculated by Schowalter et al. [1], and the 2.77 V that we obtain from our DFT calculations for relaxed materials. This opens a question about the real value of MIP for these compounds.
We used then a polar superlattice of AlN/GaN (second sample) to repeat the same measurement. In this case, the MIP difference between GaN and AlN, extracted from the electron holography result, was 1.3 V, i.e. slightly lower than in the non polar sample. We assumed that the difference could be attributed to a different strain in the structure. However, keeping in mind that AlN is under tensile strain and GaN is under compressive strain, the expected result is rather an increase of the MIP difference, which might reach up to 3 V. In summary, we conclude that current uncertainties in the AlN MIP value make it extremely difficult to extract precise information about the potential profile field in GaN/AlN heterostructures.
We have extended this work to InGaN/GaN, now obtaining more reliable results. The TEM specimen from the third sample was prepared with a gradient of thickness, so that there is a different degree of surface-induced relaxation in the 5 quantum wells. In this sample, we can show experimentally the variation of MIP with respect to strain, with the MIP of GaN and InGaN being almost equal for a completly relaxed sample. The experimental results match closely our DFT computation, including the strain dependence.
In the last sample, also InGaN/GaN but with different indium concentration, we could further confirm the effect of strain on the MIP, including a clear evaluation of the MIP difference between GaN and In0.16Ga0.84N.

Conclusion
The understanding and computation of MIP is highly important for a correct interpretation of the potential profiles measured in electron holography. In this work, we provide a theoretical and experimental evaluation of the MIP in III-nitrides. We outline the important disagreement between theory and experiments in the case of AlN/GaN heterostructures, even taking the strain into account. In contrast, we were able to provide reliable values of MIP for InGaN/GaN, showing excellent agreement between experimental and theoretical estimations, and confirming the effect of strain predicted by the calculations.

Background & aims
Gallium Nitride (GaN) microLEDs have received a lot of attention in the field of visible light microdisplays due to their interesting properties, such as high luminosity, wide wavelength range and robustness. However, their miniaturization poses a challenge due to the decrease of LED performance as the perimeter-to-surface ratio increases, a phenomenon that has not yet been fully understood. Studying carrier dynamics in these devices is crucial for understanding how recombination mechanisms affect their performance. The lateral diffusion length and carrier lifetime are therefore a major subject of interest for understanding and improving the characteristics of pixelated mesa LEDs.
In this work, we show the impact of Light Extraction Efficiency (LEE) and Internal Quantum Efficiency (IQE) independently as a function of mesa size and shape. Furthermore, lifetime measurements provide insights about the origin of IQE decrease near the mesa edge, showing the importance of diffusion coefficient and lifetime measurement techniques.
Methods
Multiple quantum well (MQW) LED structures (nGaN/5x(2.5nm InGaN/8nm GaN)/AlGaN EBL/pGaN) were patterned into 2.5, 5, 7.5 and 10 µm square and round mesas. These structures were analyzed using steady-state hyperspectral cathodoluminescence (CL) measurements at 10K and room temperature. The impact of mesa size and shape on LEE versus IQE has been explored. Additionally, Time Resolved Cathodoluminescence (TRCL) was performed with a streak camera at room temperature across a mesa to determine QW carrier lifetime and wavelength variation of the emitted light with the distance to the mesa edge.
Results
The maximum CL intensity at the center of the MQW mesas exhibits a non-monotonic trend with increasing mesa size, showing an optimal emission for the intermediate sized mesa of 7.5 µm, for both circular and square geometries. This behavior is explained by a competition between IQE (which decreases with mesa size reduction) and LEE (which increases with size reduction, with different trends for square and circular geometries), separated using the low and room temperature CL measurements. These results highlight the difficulty in properly interpreting CL intensity maps in terms of the impact of non-radiative recombination from the sides on LED mesa efficiency. However, the importance of IQE cartography at the nano scale to explore the impact of the mesa side remains significant. As already demonstrated in numerous papers, IQE decreases near the mesa wall. This decrease is mainly attributed to non-radiative recombination at the mesa edges and strongly affects smaller mesa performances. TRCL lifetime measurements across a mesa indeed show that carrier lifetime decreases near the mesa side. Furthermore, we observed a CL intensity reduction up to 3.5 µm from the mesa edge, which determines the optimal mesa size for emission. Thus, the diffusion length of carriers in the QW is one of the key parameters to minimize the impact of sidewall damage on LED efficiency. This means that a smaller diffusion length will reduce the impact of non-radiative recombination on the sidewalls on the LED efficiency.

Conclusion
This study investigates the influence of mesa size and geometry on external quantum efficiency, highlighting the significant impact of non-radiative recombination at the mesa edge. Moreover, a competition between IQE and LEE is observed, elucidated through measurements at both low (10 K) and room temperature. This competition reveals an optimal LED size for two distinct mesa geometries, offering valuable insights for the design of microLED arrays. Furthermore, our findings provide clear indications for enhancing LED characteristics, such as mitigating surface recombination at sidewalls to reduce non-radiative recombination, or minimizing diffusion length to mitigate sidewall non-radiative impacts on small mesa sizes. Since diffusion length is intricately linked to the square root of the diffusion coefficient and radiative lifetime, characterizing the diffusion coefficient becomes critical. Both steady-state and time-resolved cathodoluminescence techniques are proposed to address these parameters effectively at the mesa scale.

Nano-chemical Imaging and Spectroscopy at the Single-molecule Level

Mr. Francesco Simone Ruggeri[1]
[1]Wageningen University and Research, Wageningen, Netherlands

IM-09, Lecture Theater 5, august 29, 2024, 14:00 - 16:00

Background
Biological processes rely on a wide class of biomolecular and macromolecular machines that have nanoscale physical dimensions and whose function emerges from a correlation between their chemical and structural properties. A fundamental objective of modern analytical methods is the comprehension of how physical-chemical properties and heterogeneity of single biomolecules underlie their role in cellular function and disease. While innovative nanoscale imaging methods have been developed to characterise biomolecules, imaging microscopies are to the most part chemically blind; thus, hampering the characterisation of inhomogeneous and complex systems.

Methods
The introduction of photothermal infrared nanospectroscopy (AFM-IR) has revolutionized the field of nano-chemical analysis in a wide-open range of fields, including biological, material and polymer sciences. Here, we will present an overview of our latest development and application of AFM-IR in combination with advanced spectroscopic analysis and chemometrics, as a real breakthrough for the analysis of heterogeneous (bio-)molecular systems and materials down to the single molecule level.

Results
To illustrate our path towards single-molecule AFM-IR, we first show the achievement of single protein molecule detection of infrared absorption spectra and maps by introducing off-resonance, low power, and short pulse ORS-nanoIR. [1] This approach enables the accurate determination of the secondary structure elements of single proteins and amyloids in the amide band I region. We will then showcase the application of this unprecedented single molecule sensitivity to: i) unravel molecular structure and interactions of protein and organic molecules [2]; ii) origin of chirality in click chemistry polymers [3]. Finally, we illustrate the application of this sensitivity to probe the surface and structural properties of functional materials, such as artificial model membranes [4] and functional protein self-assemblies [5].

Conclusion
Overall, our aim is to expand the capabilities of analytical nanoscience to shed light on the structure-activity relationship of biomolecules and functional materials design.

The Environmental Impact of Large Scientific Infrastructure

Poster Group 1

Standardised energy labelling is routinely used on many of the consumer goods we interact with daily. These aim to inform customer purchasing and usage behaviours and are used by regulators to incentivise the replacement of older equipment with more environmentally-conscious choices. Currently, there is limited sustainability data available for large scientific infrastructures (such as magnetic resonance imagers, electron microscopes, and research furnaces, among many others). As a result, no scheme currently exists to fairly compare energy usage across different devices or between families of devices.

Energy usage is often not easily characterised for such infrastructure due to their diverse and multi-faceted needs; aspects may include but are not limited to, electrical draw, air compressors, water cooling, laboratory air conditioning, cryogenic gas and liquid purification/storage, as well as compute power. Usage patterns must also be considered, and optimised for equipment that is required to always be on. Some effort has been made in characterising energy consumption of hospital equipment such as MRI and CT scanners that show some parallels with scientific equipment [1-3].

The left of Figure 1 shows thermal images taken in the Advanced Microscopy Lab, Dublin of a JEOL-2100 transmission electron microscope, the ventilation output for one of the building's chillers, and a building air compressor. In the latter two, this energy is currently vented directly to the environment with no heat recovery implemented. In a cooler country such as Ireland, this means waste heat is being exhausted from instruments while central heating systems are used to heat the building's working spaces.

Datacentres occupy an increasing slice of global energy demand and associated CO2 emissions, and this is expected to grow significantly [4]. While much of this consumption is due to sectors unrelated to scientific research, modern science is driven by huge quantities of data generation and the storage and processing of this data can still result in significant energy usage. In microscopy, the data generated by modern imaging techniques can reach 200TB per hour (Figure 1, right), and will likely increase further in the future [5].

The scientific community has increasingly moved towards open data initiatives, and to support this we will present and share a fully open access tool for calculating the complex energy usage of large scientific infrastructure. Through collaboration with facility managers on a global scale, we hope to provide an open database from which a sustainability labelling system can be created, sourced entirely from community input.

With increasing global concern both with energy usage and energy efficiency, it is vital that the footprint of modern scientific research equipment be assessed and quantified to enable new auditing and labelling to be carried out. This can inform decisions made by facility managers to reduce energy consumption, leading to both lower environmental impact and financial cost. Eventually, we hope this will lead to enhanced policy direction and apply pressure to manufacturers to be more mindful in the future design and manufacture of what is today wholly unlabelled hardware.

Phase detection limits in electron holography with automatic stabilisation and direct electron detection

Dr Martin Hytch[1], Dr Cécile Marcelot[1], Dr Christophe Gatel[1,2]
[1]CEMES-CNRS, Toulouse, France, [2]University of Toulouse III, Toulouse, France

IM-03 (1), Plenary, august 28, 2024, 10:30 - 12:30

Electron holography can measure local electric, magnetic and elastic strain fields. Furthermore, the incident wave can be structured with the aid of a biprism in the illumination system for specialised interference configurations [1]. In all cases, the measurement precision is directly related to the precision with which the phase of the holographic fringes can be determined. Random errors from shot noise are related to the fringe visibility and the electron dose but also depend on the transfer characteristics of the detector and the mask used in the Fourier reconstruction:

$$\sigma(\varphi)=\sqrt{(2/N)}\times 1/V\times(MTF(q))/\sqrt{(DQE(q))}\times\sqrt{a} \quad (1)$$

where N is the number of incident electrons per pixel, V the observed visibility of the fringes, MTF(q) and DQE(q) the modulation transfer function and the quantum efficiency, respectively, of the detector at the spatial frequency corresponding to the hologram fringes and “a” a factor depending on the Fourier mask size [2]. We will test the limits of the theory and present two ways of maximising sensitivity: acquiring holograms over very long exposure times through automation [3] and with detect electron detection.

Methods

Automatically stabilised holograms were acquired on the I2TEM (Hitachi HF3300-C) microscope, operating at 300 kV and equipped with a cold-field emission gun (C-FEG), double stage, image aberration corrector (B-COR, CEOS), condenser biprism and three post specimen biprisms. In particular, two series were acquired: one on a conventional scintillator-coupled CMOS camera (OneView, Gatan Inc.) and the other on a direct detection device (K3, Gatan Inc.). Holograms covered the field of view of the detector and were adjusted to have indentical fringe spacing (5.5 pixels) using two post-specimen biprisms. Hologram phases were monitored in real-time using HoloLive! v1.1 (HREM Research Inc.) and dynamic automation was implemented through customised scripts [3]. Holograms were acquired continuously over 15 minutes (900 s) at comparable dose rates (< 9 e-/pixel/s), the cumulated intensity output every 4 s (Fig. 1a) so that the progression could be monitored. Automatic stabilisation also allows the choice of the exact position of the hologram fringes. Systematic errors were investigated by recording holograms with different initial phase values [4].

Results

The phase error, measured by the standard deviation in a region of vacuum, diminishes over time as expected by the theory (Fig. 1b). Indeed, direct detection provides a spectacular improvement in the precision of the phase. However, in both cases, the phase error reaches a plateau, with little improvement beyond a certain dose. We will show the cause of the systematic errors and how they can be corrected.

Conclusions

The theoretical limit for the phase precision can be obtained using dynamic automation and direct electron detection. We will show how systematic errors can be removed by controlling the incident illumination for an ultimate precision of 1 mrad at nanometre spatial resolution.

Poster Group 2

Background: The generation of chemical maps of sub-cellular structures in biological samples is one important tool to identify and localize accumulating ingested particles, drugs or metal tagged biomarkers. By correlating this chemical information obtained by spectroscopical methods like x-ray spectroscopy, etc. to an ultrastructural image obtained by light or electron microscopy the underlying physiological processes can be investigated. However, the better the lateral resolution of the chemical mapping, the lower the signal detected per voxel, oftentimes leading to inaccessibility of certain markers for chemical imaging in cells and tissues. In this regards, secondary ion mass spectrometry (SIMS) is a powerful technique for analyzing surfaces at high spatial resolution, owing to its ability to detect all elements from H to U and to differentiate between isotopes, its excellent sensitivity and its high dynamic range. Our group focuses on the development of multimodal imaging platforms giving access to correlative investigation approaches by directly linking SIMS data with data obtained by other analytical (such as Energy-Dispersive X-Ray Spectroscopy) or imaging techniques on the same instrument (e.g. secondary electrons (SE), back-scattered electrons (BSE) or images of the transmitted ion or electron beam (STIM, STEM)). The possible combinations are dependent on the sources and detectors available on these platforms.
Methods: Currently, several focused ion beam platforms with or without an additional electron column are available and are equipped with at least a secondary electron detector and LIST's magnetic sector SIMS system (FIB-SIMS with < 15 nm spatial resolution). These instruments use various primary ion beam species, such as Ga [1], He / Ne [2-3], Cs [4] as well as Si / Au / Li / Bi [5]. Our magnetic sector SIMS system is equipped with a continuous focal plane detector technology allowing parallel detection of all masses for each single pixel in the scanned region of interest. One instrument is also equipped for imaging the transmitted beam information and can be operated at RT and under cryogenic conditions facilitating the analysis of beam sensitive samples and frozen samples.
Results: A number of examples from different application fields (nanotoxicology, environmental pollution, water organisms etc.) will be presented.
Conclusion: The performance of the different instruments will be discussed with a focus on new developments, different SIMS acquisition modes (mass spectra, depth profiling, 2D and 3D chemical imaging) and their applicability for biological samples including frozen-hydrated specimen.

Poster Group 2

Ceria-based materials find their applications in various fields. Due to their oxygen deficiency at the surface the ceria nanoparticles are especially attractive catalysts [1]. By introduction of dopants into the ceria lattice the catalytic performance of ceria nanoparticles can be even further increased. To fine-tune the catalytic performance though the insights into the structural-properties relationships in the materials advanced TEM with spectroscopy should be applied. 2D and 3D multimodal STEM is of crucial importance to understand the structure and chemistry of doped catalysts at the nanoscale and to enable the targeted approach to the materials development.

In this work we combined EDX, EELS and electron tomography to investigate the local chemistry of Cu-doped ceria (Cu:CeOx) catalyst exhibiting superior performance for low temperature CO oxidation with respect to the undoped CeOx material. EELS both in 2D and 3D evidenced the elegant double core-shell structure of the undoped CeOx nanorod (see the figure), most likely related to the large amount of voids inside the particle: a shift of the Ce M4,5 edge onset as well as the white line ratio variation was clearly observed in the EELS spectrum allowing to distinguish between Ce4+ and Ce3+. In contrast to the previous work [1] where to gain the similar insights the monochromated 120kV setting was applied in the present study the experiment did not require the use of the excited monochromator and the lowered HT making the experimental work easier. Simultaneous EELS-EDX investigation was performed to study the Cu:CeOx material. Even though the CuL2,3 edge is visible in the EELS spectrum, its overlap with the fine structure of Ce inhibits the reliable STEM-EELS mapping of Cu in Cu:CeOx. EDX in this case clearly located Cu locations within the nanorod while STEM-EELS evidenced the Ce3+ oxidation state of cerium, highlighting the high amount of oxygen vacancies which can be correlated to the superior performance of the doped ceria catalyst.
To sum up, both EELS and EDX giving the access to the local chemical information, in combination with the electron tomography, giving the access to the 3D information, are of great help while investigating catalytic nanoparticles. We highlighted here the unique insights of the multimodal and multidimensional approach by an example of doped ceria catalyst investigation.

Background incl. aims:
Microstructural investigations provide engineers with information to computationally predict the performance of components and electron microscopy is a well-versed technique for analyzing micro/nanostructural features. Two types of electron microscopes are commonly used and provide complementary information: Transmission Electron Microscope (TEM) at the micro/nanoscale and Scanning Electron Microscope (SEM) at the macro/mesoscale. Historically, Scanning Transmission Electron Microscopy in Scanning Electron Microscope (STEM-in-SEM) techniques were predominantly used by biologists due to their user-friendly nature and their ability to analyze specimens at low accelerating voltages (30 kV or below). This made STEM-in-SEM techniques complementary to conventional TEM ones as the latter generally use high accelerating voltages (~200 kV). Recent advances in electron guns and electromagnetic lenses have sparked growing interest in STEM-in-SEM techniques across various scientific disciplines. However, researchers often face challenges in establishing the precise imaging conditions required to obtain comprehensive micrographs, thus limiting their interpretation and analysis.
Methods:
In this study, we propose a novel STEM-in-SEM approach, which aims to overcome the practical limitations of traditional techniques for microstructural characterization in thin foils. The technique leverages an advanced detector designed to replicate TEM-like characterizations while minimizing the presence of artifacts that commonly hinder comprehensive analyses. In addition, this STEM-in-SEM technique benefits from On-Axis Transmission Kikuchi Diffraction (On-Axis TKD), thus allowing diffraction pattern acquisition with a high signal-to-noise ratio.
Results:
First results already show the possibility to acquire diffraction patterns and to image dislocations under modulable bright-field and dark-field conditions.
Conclusion:
By implementing this pixelated STEM-in-SEM technique, we anticipate significant advancements in the field of microstructural characterization by obtaining TEM-like and TEM-complementary information. Ultimately, the developed technique should facilitate studies to obtain detailed information about thin foil specimens, thereby contributing to a broader range of scientific applications.

Background
Nanoparticles find uses in a plethora of applications ranging from food preservation and pharmacology to industrial catalysts. Obviously, the first question which is asked when it comes to nanoparticles is the size. However, several aspects of nanoparticles dictate their shape and function. This includes morphology, chemistry, crystallography, oxidation state and environment.
When it comes to providing answers on these topics, transmission electron microscopy (TEM) has been the go-to tool. Modern microscopes easily provide answers on all these topics. However, there are three main challenges. 1) the structure of nanoparticles is not always unaffected by the exposure to high-energy electron beams; 2) to provide statistically relevant information, a large number of nanoparticles should be analyzed; 3) the environment inside the TEM is most often not the same as that where the nanoparticles are used. To accommodate the beam sensitivity, we can lower the electron dose rate to levels where the effect is negligible or otherwise easy to accommodate for. To improve the statistical significance, we can count large numbers of particles and use automated data analysis approaches. Lastly, to image the particles under realistic conditions, we can control the environment in which we image them.

Methods
Here we use environmental transmission electron microscopy to monitor the size, shape and dynamics of nanoparticles relevant for catalytic applications. We focus particularly on gold nanoparticles on cerium dioxide which catalyzes the oxidation of carbon monoxide. Using a CMOS based OneView camera from Gatan, we have acquired data series at varying electron dose rate and under different environments. Using these datasets, we evaluate the signal to noise ratio (SNR) based on different models. Furthermore, we estimate the usability of the structure similarity index measure (SSIM) to detect structural changes of the gold nanoparticles and how prefiltering and adjusting can help our data analysis. We compare these results to measurements performed using data analysis by convolutional neural networks trained on simulated data [1, 2].

Results
Using three models of the signal-to-noise ratio we estimate the interpretability of HRTEM images and rate the measured SNR against the output of data analysis based on convolutional neural networks. SNR(I) is the traditional method of calculating SNR. SNR(II) uses the standard deviation of the nanoparticle and background region separately. SNR(III) takes the high intensity variation of phase contrast images into account. Figure 1 top pane shows images extracted from sequence acquired at increasing dose rate. The bottom pane shows the SNR calculated based on different models showing data from the entire image series. We have further pursued the analysis of Au nanoparticle structure as a function of the environment.

Conclusions
Determining the SNR of an image can tell us something about the interpretability and if it makes statistical sense to continue a more thorough analysis. Here we have attempted alternatives to the traditional method of determining SNR which may not be well-suited to estimate the interpretability of HRTEM images. We have correlated this with data analysis based on convolutional neural networks.

Poster Group 1

The Selectris energy filter was introduced in 2020 [1]. This filter comprises a large tapered prism and ten multipoles most of which are implemented as dodecapoles. These enable stable and superior correction of non-isochromaticy and image distortions. Now, we are developing an EELS spectrometer based on the technology of this filter.
Compared to energy filtered imaging, the optics of EELS has the additional challenge that a broad range of electron energies (up to several thousands of eV wide) must be simultaneously transferred through the microscope and through the spectrometer, from specimen to detector, without introducing chromatic blur or chromatic distortions. This is a non-trivial task, especially when we desire that such transfer is maintained across different microscope settings (different camera lengths) and across different spectrometer settings (different dispersions and different spectrum offsets). Maintaining this can only be ensured by closely integrating the optics of the microscope and of the spectrometer, to keep the chromatic defocus in the microscope matched with the focus of the spectrum. Otherwise, the superior performance offered by the tapered prism and ten multipoles could only be fully enjoyed at (one or) a few specific experimental settings, and would be lost when switching to other camera lengths or other dispersions or other energy offsets.
Compared to the Selectris energy filter, our EELS spectrometer has the following additional functionalities: (i) above mentioned integration between the optics of the TEM and the spectrometer, (ii) a dedicated detector optimized for fast read-out, low-noise, and radiation hardness, (iii) fast electrostatic elements (shutter, bias tube, deflector) for near-simultaneous acquisition of multiple (dual, triple, ...) regions of the EELS spectrum, and (iv) fully automated EELS tuning routines.
Figure 1 illustrates the optical performance of our spectrometer. It shows triple-EELS for $DyScO_3$ taken at 60kV, monochromated, 30mrad semi-convergence angle, 5mm spectrometer entrance aperture, and at five different camera lengths. The top panel shows data acquired without correction for the chromatic effects: clearly, the chromatic blur leads to resolution loss at the higher energy losses and at the smaller camera lengths. Bottom panel shows data acquired with on-the-fly correction of the chromatic effects: resolution is ensured across all settings, even for the challenging case of ΔE=1300eV at 60kV, and semi-collection angle of 49mrad (CL=25mm).
The stability of the Selectris, the full automation of the EELS tuning, and the integrated correction for chromatic effects greatly improve the ease-of-use and productivity of the new spectrometer.

Materials characterization of recycled batteries (black mass): automated quantitative phase classification in 3D

Ria Mitchell[1], Mr Andy Holwell[1], Dr Richard Taylor[1], Dr Eddy Hill[1]
[1]Carl Zeiss Microscopy Ltd, Cambourne, UK

Poster Group 1

Background incl. aims
Recovery of valuable raw materials from spent batteries (e.g., Cu, Al, Fe, Mn, Ni, Co, Li, P, etc), is important in the shift away from environmentally damaging raw material extraction. The black mass production process starts with the collection and disassembly of the battery. The procedure that follows is akin to the processing of a mineral ore. The disassembled components are shredded to produce the black mass powder, containing the valuable metals. Most processes then treat the black mass with reagents to separate the individual metals. The efficiency of any such process depends on the knowledge of the composition of the black mass, of any impurities it may contain, and how said impurities interact with the reagents to passivate the recovery of the metals. Therefore, the efficient recovery of metals from black mass is dependent on the detailed understanding of its composition. Here, we present novel bulk phase analytical techniques for the 3D characterization of black mass. The use of automated phase classification via X-ray microscopy highlights details of the chemistry and morphology of its constituents non-destructively in 3D, therefore improving the characterization process immeasurably.

Methods
We present a combined workflow using 3D X-ray imaging via a ZEISS Xradia 620 Versa X-ray Microscope (XRM), and advanced reconstruction techniques to enhance contrast, reduce noise, and resolution recovery using the ZEISS Advanced Reconstruction Toolbox (ART). Finally, we use an automated 2D and 3D quantitative phase classification approach in the Scanning Electron Microscope (SEM) and XRM using Mineralogic 2D and 3D, respectively. This combination of approaches in a correlative workflow contribute towards our better understanding of the black mass.

Results
We identify a variety of components of different densities, including foils, separators, and both liberated and non-liberated cathodes containing electrode particles (Figure 1). To enhance the data further, we use modules of the Advanced Reconstruction Toolbox: firstly, ZEISS DeepRecon Pro software, a machine-learning based reconstruction option for advanced de-noising and enhanced contrast. Reconstructing data in this way allows us to collect fewer projections meaning scans are faster and more samples can be imaged. In the black mass, there is a marked improvement in the quality of the data: noise is significantly reduced, and contrast is improved so individual electrode particles are identified with more clarity. Secondly, we apply ZEISS DeepScout software. DeepScout is an AI powered method to upscale scans to a larger field of view whilst preserving high resolution, a form of Resolution Recovery. We increase the field of view by over 2x, enabling us to observe electrode particles at high resolution over a larger area. Both approaches lead to segmentations and quantification representative of a larger sample area without compromising resolution. To quantify the different components within the black mass, we use two complementary approaches: ZEISS Mineralogic 3D and 2D. Mineralogic 3D classifies materials in the 3D XRM data using deep learning to execute automated mineralogy and phase identification. The materials classifier uses the XRM data

histogram following DeepRecon Pro reconstruction and identifies two types of battery (LFP and NMC) and two types of foil (Al and Cu), as well as graphite and Al polymer separator. Therefore, we can quantify each of these components and visualize them in 3D to identify the location of valuable retrievable elements in the black mass. This is further supported by complementary analyses via ZEISS Mineralogic 2D. This is obtained using an SEM with the assistance of the chemical SEM-EDS data, allowing for quantitative phase analyses rather than singular chemical elements alone. In this approach we are also able to quantify the different phases, and understand the location and quantities of recoverable elements such as lithium, manganese, cobalt, aluminum, copper, and iron. Both results indicate that in fact two different battery types are present in this sample, as well as two different types of foil when it was thought that the foils were removed during an earlier part of the black mass production process.

Conclusion
Our results show that it is easily possible to identify and quantify recoverable phases from black mass, which will help towards the battery recycling process. These advanced characterization techniques are imperative to ensure the black mass production process is reliable and exact in a world where valuable constituent recovery from batteries will become essential going into the future.

Multi-scale characterization of vitamin B2 (riboflavin) supplements using X-ray Microscopy, SEM, and automated phase analyses

Ria Mitchell[1], Dr Darragh Murnane[2], Mr Andy Holwell[1]
[1]Carl Zeiss Microscopy Ltd, Cambourne, UK, [2]University of Hertfordshire, Hatfield, UK

Poster Group 1

Background incl. aims
Riboflavin is a water-soluble micronutrient that is essential for the reproduction of cells and growth in the human body, as well as helping to prevent inflammation and ageing. It naturally occurs in a variety of foods including fruit, vegetables and meats, however it is regularly incorporated into vitamin or dietary supplements to bolster healthy lifestyles. Recently, it has been found to potentially be a natural alleviator of migraines due to its preventative effects of migraine symptoms such as neuroinflammation, and now many migraine-relief specific versions of the nutrient exist and can be purchased 'off the shelf'. However, while most pharmaceutical products are highly regulated, dietary supplements such as these have less stringent regulatory assurances. The most popular cost-effective method of their production is from fermentation, where the active nutrient is subsequently mixed with other components such as anti-caking agents, fillers, and lubricants to homogenize the mix and ensure enough of the vitamin enters the body. However, different manufacturers include differing components in variable quantities, and there is variation in their manufacture. Therefore, a full multi-scale characterization of these supplements is important to (i) understand the spatial distribution and morphological characteristics of the different components, (ii) to quantify the active components, and (iii) to understand quality assurance based on the variable manufacturing processes involved with production of these supplements.

Methods
Here, we have studied two different vitamin B2 supplement capsules from two different manufacturers to characterize and quantify the different components in 3D. Capsule 1 contains riboflavin (active ingredient), silicon dioxide (likely as anti-caking agent), and Mg stearate (likely as lubricant), and capsule 2 contains riboflavin (active ingredient) and Mg stearate (likely as lubricant) only. We use X-ray Microscopy (XRM) to image the powders non-destructively in 3D, and apply various advanced reconstruction approaches to enhance visualization of the data: DeepRecon Pro, a machine-learning based reconstruction approach to reduce noise, improve contrast, and shorten scan time/increase throughput; and PhaseEvolve, which uses AI algorithms to enhance the data so that it uncovers different material contrasts uniquely revealed by XRM. Finally we use an automated phase classification and segmentation method to quantify the different components in 3D. This approach not only introduces the benefits of using 3D imaging to study pharmaceuticals, but sheds light on the structural morphology of the active components in vitamin supplements. Additionally, we use SEM in a correlative workflow for 2D imaging and chemical analyses of individual components.

Results
Both capsules' powders were imaged in 3D at the multi-scale using a ZEISS Xradia Versa 520 XRM. Initial observations reveal that the morphology of each capsules' powders are indeed very different, with large morphological and structural differences, suggesting that the powders were likely produced by two different production methods: spray drying and granulation. DeepRecon Pro

significantly improves the quality of the data compared with tradiaitional reconstruction methods (e.g., filtered back projection) by reducing noise and improving contrast. PhaseEvolve further enhances the contrast between the different powder components, and we are able to identify an additional 'binder' phase which is not identifiable from filtered back projection data alone, therefore contributing towards a more accurate segmentation of phases and data. Complementary analyses via Mineralogic 3D for phase classification indicates that this new binder phase is Mg stearate which is the 'glue' holding riboflavin particles together as agglomerates, and allows us to segment and quantify this phase fully in 3D. Further, using Mineralogic 3D we identify a filler (calcium phosphate) in capsule 1 which is not listed on the ingredients.

Conclusion

The results presented here show that non-destructive 3D imaging via X-ray Microscopy (XRM) and associated advanced reconstruction techniques are a useful tool for understanding the composition of vitamin supplements. We find previously unobservbable phases using these techniques, and are able to identify and quantify components which are not listed on the ingredients. This approach could be extended to other pharmaceutical materials to maintain regulation.

New paradigm for ultra-low-dose high-resolution imaging through a dedicated event-driven analytical ptychography methodology

Dr. Hoelen L. Lalandec-Robert[1,2], Prof. Dr. Jo Verbeeck[1,2]
[1]Electron Microscopy for Materials Science (EMAT), University of Antwerp , Antwerp, Belgium,
[2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium

Poster Group 2

Recently, significant advances in scanning transmission electron microscopy (STEM) have made it a viable solution for the high-resolution imaging of beam-sensitive specimens such as 2D materials, ordered nanoporous particles, viruses or protein crystals. In particular, the development of dose-efficient computational imaging approaches such as analytical ptychography, e.g. in the form of the Wigner distribution deconvolution (WDD) and side-band integration (SBI) methods, have permitted the direct retrieval of the projected electrostatic potential with the highest achievable signal-to-noise ratio [1]. Furthermore, with the introduction of event-driven detectors (EDD), the ultra-low-dose measurement (<100 e-/Å2) of the far-field electron intensity was enabled as well [2].

In this work, we present developments of WDD and SBI aiming to improve their performances in imperfect recording conditions, e.g. by including geometric aberrations, partial coherence and the modulation transfer function (MTF) of the camera. We also introduce a scan-frequency partitioning algorithm permitting the computationally heavy implementation of those methods in a RAM-limited device, such as a commercial graphics processing unit (GPU). Moreover, we evaluate the capacities of analytical ptychography to transfer a range of frequency information, with dependence on both the scan sampling and the illumination parameters, on the basis of the Cramér-Rao lower bound [3]. As such, an updated metric for the probe overlap requirement of electron ptychography is presented.

Additionally, we establish the guided progressive reconstructive imaging (GPRI) method, which constitutes a new framework to perform WDD and SBI through the direct treatment of a stream of electron events provided by an EDD. This process is purely cumulative, as each count leads to the addition of a single contribution to the result, selected from a set of pre-calculated libraries. GPRI should thus permit reaching the best achievable dose-efficiency and processing speed in live ptychography, in particular through a direct implementation in the field-programmable gate array (FPGA) unit of the EDD and thus with no need for a prior transfer of the event data to a separate computer, which currently represents the main bandwidth limitation in other approaches. This method can be furthermore supplemented with recording strategies optimized for damage mitigation [4,5].

The methods developed in this work are tested by means of multislice frozen phonon simulation, allowing the exploration of different experimental parameters, such as dose, probe focus, specimen thickness, source size and focus spread. Preliminary experimental demonstrations are carried out as well.

Figure: examples of analytical and iterative ptychography results to recover the projected potential μ or a transmission function T (complex exponential of μ). The simulated STEM scan was performed on a single-layer MoS2 specimen. The chosen semi-convergence angle α was 30 mrad and the acceleration voltage U was 60 kV. Two cases were investigated: the use of a perfectly focused probe

and of an overfocused probe, with focus f equal to 50 nm. Dose limitation was included by realistic representation of single counts, whose total number per frame was determined by Poisson statistics. Note that, for the focused probe case, an average number of 4 counts per scan position leads to a dose of about 164 e-/Å2 (i.e. ratio of total electrons used by scanned surface).

This work received funding from the Horizon 2020 research and innovation programme (European Union), under grant agreement No 101017720 (FET-Proactive EBEAM).

Poster Group 1

Background
Inward-rectifier potassium (Kir) channels are a group of integral membrane proteins that selectively control the permeation of K+ ions across cell membranes. The small outward K+ current through Kir channels controls the resting membrane potential and membrane excitability, regulates cardiac and neuronal electrical activities, couples insulin secretion to blood glucose levels, and maintains electrolyte balance1. All Kir channels are tetramers and share characteristic structural features. They have a canonical pore-forming transmembrane domain (TMD) made of two transmembrane helices separated by a K+ ion selectivity filter and a large cytoplasmic domain (CTD) containing both N and C termini. The CTD extends the ion conduction pathway and provides docking sites for regulatory ions, proteins, and ligands2. The strong inward-rectification mechanism results from a block on the cytoplasmic side of the channels by endogenous polyamines and Mg2+ that plug the channel pore at depolarized potentials. The blockers are then removed from the pore when the K+ ions flow into the cell at hyperpolarized potentials. In addition to being inwardly rectifying, the gating of Kir2.1 channels are selectively activated by the lipid phosphatidylinositol 4,5-bisphosphate (PIP2). The physiological importance of these channels is underpinned by the fact that mutations in these proteins cause a wide range of pathologies. In previous published work, we used cryo–electron microscopy (cryo-EM) combined with image analysis to elucidate the structure of a human Kir channel, Kir2.1 in the closed state3. Furthermore, computational investigations reveal crucial conformational movements, including compaction of the structure and opening movements at the interface between the TMD and CTD, which could facilitate the binding of PIP2. In order to understand the gating mechanism, both structures of Kir2.1 in the closed and open state are needed.
Methods
A total of 9944 micrographs were collected on a Titan Krios G4 microscope operated at 300 kV equipped with Falcon4 and SelectrisX image filter. After a visual inspection to remove poor-quality micrographs, the movies were motion-corrected and dose-weighted (MotionCor2) and contrast function parameters were estimated (CTFFIND4) on 6961 selected micrographs. A total of 781,076 particles were automated picked (SPHIRE-crYOLO). The extracted particles were subject to one round of 2D and 3D classifications (RELION). A map containing 187,153 particles were subjected to 3D Auto-Refine, CTF-refinement and particle polishing. The polished particles were submited to a 3D non-uniform refinement (cryoSPARC)
Results
Here we present the cryo-EM structure of the human Kir2.1 channel complexed to PIP2 in the open state (Fig.). and provide the final cryo-EM map of the Kir2.1/PIP2 complex at 2.85 Å resolution. Preliminary atomic structure of Kir2.1/PIP2 complex was build from the cryo-EM map and revealed the PIP2 binding site.
Conclusion

Comparative structural analysis of the Kir2.1/PIP2 complex (open state) with apo-Kir2.1 (closed state) and in silico studies reveal the structural changes that lead to channel opening. Moreover, the structure of the Kir2.1/PIP2 complex highlights the role of secondary anionic binding site for channel opening. These data will help to understand the pathological mechanisms associated with mutations in the Ki2.1 channel

Combining in-situ synchrotron and electron microscopy techniques to study NiFe catalysts for CO2 methanation

Dr Manfred Erwin Schuster[1], Dr Pilar Ferrer[2], Dr Rosa Arrigo[3]
[1]Johnson Matthey, Sonning Common, United Kingdom, [2]Diamond Light Source, Didcot, United Kingdom, [3]University of Salford, Manchester , United Kingdom

Poster Group 1

Background
Nickel-based catalysts on various supports have been widely studied for CO2 methanation due to higher activity, nickel's natural abundance, and relative low cost. However, most Ni-based catalysts suffer from deactivation due to carbon deposition, oxidation, sintering, and chemical poisoning. Recently, significant progress has been made in the exploitation of novel/modified Ni-based catalysts for CO2 methanation. As far as the support is concerned, the effect of various supports (CeO2, ZrO2, TiO2, MgO and mixed oxides) on Ni-based catalysts was studied with the goal to increase metal dispersion as well as induce an electronic effect for improving the selectivity towards methane over CO. In our collaborative study we investigated the effect of promoters of both support and active metal on hydrotalcite derived Ni/Al2O3 catalysts. From our catalyst screening experiments, we were able to select TiO2 as best support modifier and Fe as an active metal promoter. Amongst the prepared novel catalysts for CO2 methanation Ni-Fe/Al2O3 and Ni/CeO2-TiO2-ZrO2-Al2O3 were found to be exceptionally active and relatively more stable than commercially available catalysts (Ni/Al2O3). We apply multi-length-scale structural characterization in operando to these systems to gain mechanistic insights of general validity.

Methods
In this contribution we will combine in-situ TEM gas phase experiments with in-situ hard X-ray experiments to reveal the changes of the electronic structure the catalysts undergo under reduction and methanation conditions. We will present a comparative analysis of the following systems: Ni/Al2O3, Ni-Fe/Al2O3, Ni/CeO2-Al2O3 and Ni/CeO2-TiO2-ZrO2-Al2O3. In-situ TEM experiments will be complimented by in-situ gas phase experiments carried out on the i14 nanoprobe beamline utilizing an adapter which allows us to study the sample under the same experimental conditions [1]. This capability allows us to carry out multilength scale in-situ experiments by combined TEM and nanoprobe XANES, thereby linking dynamics observed on a nm- scale with those at the um scale. Mass spectrometer data acquired during the experiments will be used to correlate structural changes with catalytic activity.

Results
Figure 1 shows, as an example, the changes Ni-Fe/Al2O3 undergoes from its fresh form, during reduction at 500°C in H2/He and during reaction conditions at 300°C in a mixture of CO2, H2 and He. The distribution of Ni metal and oxide species as well as the changes in Fe oxidation state as function of the experimental conditions are obtained by in situ EELS mapping. Two regions can be identified: Metallic Ni nanoparticles are exsolved during the hydrogenation step (blue square in Figure 1 a, c), which contain a small amount of Fe; Highly dispersed NiO species are collocated with Fe(II)/Fe(III) species (black and red squares in Figure 1a, c and corresponding EELS spectra in Figure 1 e)). In addition, operando XANES unveil the presence of metallic Ni and Fe species, more so in the core of the particle (Figure 1 f, g).

Conclusion
The comparative analysis of these systems allows to clarify the role of the heteroatoms on the electronic structure of Ni. We will show that similarly to Fe, Ce acts as a sacrificial O-scavenger, maintaining Ni in a metallic state during the methanation thereby favouring methane formation over CO. We will also clarify the role of TiO2 in preserving a high dispersion of Ni.

Background and aims
There is a strong interest in the development of efficient solid-state UV-C sources in the 220-270 nm range due to their powerful germicidal properties. Light emitting diodes (LEDs) based on the AlGaN semiconductor system are the most promising approach, but the early stage of development of the AlGaN technology still presents challenges, such as inefficient p-type doping and resistive ohmic contacts, resulting in low efficiencies. An approach that circumvents these material limitations is the use of electron beam pumped lamps; with a UV-emitting material (anode) housed in a vacuum tube. High-energy electrons are emitted from a cold cathode and accelerated towards the semiconductor anode, generating free carriers. Unlike LEDs, electron beam pumped lamps don't require p-type doping or contacts. To further enhance device performance, the use of AlGaN quantum dots (QDs) as radiative recombination centers is very promising. The three-dimensional (3D) carrier confinement within QDs prevents carrier diffusion towards non-radiative centers, leading to improved radiative efficiency even at high temperatures. However, samples emitting at wavelengths shorter than 270 nm present broad or bimodal spectra. It is crucial to minimize bimodal emission or emission line width to achieve highly efficient devices for disinfection.
In this work, we investigate the origin of the bimodal emission in Al0,14Ga0,86N/AlN QD superlattices designed for electron beam pumped UV emitters. We propose a comprehensive analysis combining 2D-3D scanning transmission electron microscopy (STEM), atom probe tomography (APT), cathodoluminescence (CL) spectroscopy associated to 3D simulations of the electronic structure.
Methods
The sample consists of 100 periods of Al0,14Ga0,86N/AlN self-assembled Stranski-Krastanov QDs deposited on commercial 1-µm-thick (0001)-oriented AlN-on-sapphire templates by plasma assisted molecular beam epitaxy (MBE) [Fig.1(b)]. 2D and 3D structural properties of the samples were studied by bright field (BF) and high-angle annular dark field (HAADF) STEM imaging using a probe-corrected Titan Themis (Thermo Fisher Scientific) operating at 200 kV. Compositional information of the sample was measured by laser-assisted atom probe tomography using a CAMECA FlexTAP instrument. Cathodoluminescence measurements were carried out using an Attolight CL-dedicated SEM microscope. The electronic structure of the QDs was modelled using the Nextnano3 8-band k·p Schrödinger-Poisson equation solver with AlN and GaN parameters and experimental dimensions and composition as inputs parameters.
Results

The top-view CL [fig.2(a)] presents a predominant line at 290 nm and a secondary emission at 305 nm. The SEM (scanning electron microscopy) image associated to the λ-filtered CL map [Fig.2(b)] evidences that the emission at longer wavelengths is linked to pits.
To gain deeper understanding of the structural and optical effects associated with the pits observed at the surface, we performed CL and transmission electron microscopy (TEM) characterization on the same TEM sample. Figure 3(a) presents a λ-filtered CL map of a zoomed region with two wavelength emission domains superimposed to a HAADF-STEM image of the same region. The associated HAADF-STEM image [Fig. 3(b)] shows that the longer wavelength emission appears associated with 3D conical structures.The zoomed BF-STEM image ([fig.3(c)] of a conical structure shows that it appears at the interface between the AlN buffer layer and the superlattice with inclined facets around 30° with the (0001) plane at the edge. To gain further insight into the nature and compostion of the conical domains, electron tomography has been performed and shows the propagation of the shallow pit profile through the superlattice [Fig.4(a)], with a brighter chemical-related contrast indicating a higher Ga content compared to the surrounding regions. In addition, HAADF-HRTSEM has allowed to determine the dimension of QDs in conical and homogeneous (non conical) emission regions.
APT was performed to gain combined 3D structural and quantitative compositional information within the conical structure. Figure 4(b) displays an APT Ga map; which enables the visualization of the QD planes, as they are those containing Ga. The upper part of the tip exhibits a homogeneous region with flat QD planes. However, a significant portion of the tip contains a threading defect which corresponds to the faceted step present at the boundary of the cone-shaped extended defect. Focusing on the APT analysis of 5 QD planes [Fig. 4(c)] located on the lower part of the sample, the Ga-atom planes exhibit a bending angle of approximately 30°, corresponding to the behavior observed in bright field (BF) STEM [Fig.4(d)]. Projected side and top view Ga map density for the 5 QD layers are presented in the figure 4(e) and (f), respectively. We see that the QD layers exhibit a Ga enrichment towards the 30° facet. We choose to quantify the composition of the QD-SL in the defect and homogenous region by the comparison of the Ga density. Considering that the non-defective regions contain Al0.14Ga0.86N QDs (nominal concentration deduced from growth conditions), we deduce that the faceted region should contain Al0.07Ga0.93N QDs, which should red shift the emission wavelength.
To investigate whether the chemical and morphological changes of the QD population within the entire structure are responsible for the emission bimodality, we conducted 3D simulations of the electronic structure of AlGaN/AlN QDs by solving the Poisson and Schrödinger equations using Nextnano3 within the conical and homogeneous regions. Dimensions and composition in (i) homogeneous [Fig.5 (a)], (ii) conical area [Fig.5 (b)] and (iii) at the frontier of the defect area with 30°-facet [Fig.5 (c)] are used as inputs parameters for simulations. The direct comparison between simulated and experimental wavelength in both regions [Fig. 5(d)] confirms that the bimodality emission is due to the different size and chemistry of the dots within the defect and at the defect boundary.
Conclusion
The bimodal emission is attributed to the presence of a secondary population of quantum dots located within cone-like structural defects. These defects emerge at the initial interface between the AlN buffer layer and the QD superlattice and propagate vertically. They are associated to a dislocation featuring a strong strain field, thereby facilitating the generation of a shallow pit characterized by 30° faceted boundaries.

Poster Group 1

Background
Exsolution enables direct growth of transition metal nanoparticles embedded in metal oxide supports, which are attractive for various electrochemical and catalytic applications for energy conversion and storage. In exsolution, the transition metal is first incorporated into the metal oxide matrix, and exsolve as metal nanoparticles under reducing conditions by diffusion, reduction, nucleation and growth. Foreign cations in perovskites usually substitute the A- or B-site depending on their relative size with respect to the host species. Small transition metals are thus commonly expected to prefer the B-site. However, the exsolution process is observed to be relatively fast, which is unexpected based on the low diffusivity of the B-site with strong covalent bonds to the oxygen octahedra. In similar perovskite systems, it has been suggested that small transition metals favor an interstitial position with square planar coordination adjacent to A-site vacancies [1], as illustrated in fig (a). In this work, the Ni position in A-site deficient La-doped $SrTiO_3$ in the initial stages of exsolution is explored using semi-quantitative STEM. The knowledge obtained will support the development of a microscopic model of the exsolution phenomenon, which can be applied for optimized process strategies for energy conversion and storage applications based on the anchored nanoparticles.

Method
Powders with nominal stoichiometry $La_{0.2}Sr_{0.7}Ti_{0.9}Ni_{0.1}O_3$ were synthesized by solid-state reaction. Exsolution of nickel metal particles were performed by reduction under 5% H_2 in Ar atmosphere at 800 °C for 30 minutes. The relatively large difference in atomic number (Z) between O (Z=8) and Ni (Z=28) is exploited in the STEM images by projecting the matrix along the <100> orientation to isolate the potential interstitial Ni position on the oxygen column. A FEI Titan G2 60-300 instrument with a DCOR Cs probe corrector was operated at 200 kV with a convergence angle of 33.1 mrad to obtain an ABF image from collection angles of 8-34 mrad, suitable to image the lighter element columns. The Z-dependency was identified using the multislice method as implemented in the abTEM package [2] by simulating STEM images with the experimental conditions for a thickness-defocus series of an ideal $SrTiO_3$ structure, and for an atomic model with an interstitial Ni and A-site vacancies. The experimental column intensities were determined by fitting 2D Gaussians using the Atomap package [3]. A statistical-model based approach based on Akaike and Bayesian Information Criterion (AIC, BIC) was utilized for fitting the intensity histogram to identify the most likely independent intensity contributions. The semi-quantitative approach proposed by Aarholt et al. [4] was adopted to identify the point defect from the relative intensities of the columns.

Results
As a rule of thumb, the intensity of ABF images is proportional to Z^a with a = 1.3 which originates from a balance between elastic and thermal scattering that are most dominant for lighter and

heavier atoms, respectively.[5] However, changes in collection angle, thickness, defocus, and atomic number may alter this Z-dependency. By simulating a thickness-defocus map of ABF images of the ideal <100>-orientated $SrTiO_3$ structure with the employed collection angles, a linear Z-dependency is identified from the ratio between the intensities of the Ti- and Sr-columns, as seen in fig 1(b). From the simulated ABF image of the atomic models with interstitial Ni located on the O-column in fig (c), a split in a histogram of integrated intensities of the columns is expected to be observed in the experimental ABF image.
In fig (d), the experimental ABF image of the exsolved sample on the <100> orientation is presented with the inset illustrating the location of the 2D Gaussians fitted to the atomic columns. A statistical-model approach based on the integrated classification likelihood is adopted to avoid under- and overfitting the histogram of intensities, and to avoid biased interpretations. From fitting an increasing number of Gaussians, one calculates a score based on maximizing the log-likelihood function of the fit while penalizing the number of components and their complexity, which in our case, was done according to AIC and BIC. The log-likelihood function has a negative pre-factor, meaning a lower score indicates a higher likelihood of a valid physical description of the experimental data by the model. Both criteria agree on a three-component model for the optimized fit of the histogram of the integrated intensities of the 2D Gaussians of the O-column, seen in fig (e) and (f). There is, however, no guarantee of a physical validity of the model despite a good fit, but from the interpretation of the ratio of the mean value of component 2 and 3, the ratio becomes 1.23 ± 0.14 which results in an average Z of 9.83 ± 1.11 given a linear Z-dependency and interpreting component 2 as the O-column. The calculated value of 1 Ni for every 10 O provides an average Z of 9.82. While the absolute quantification of the number of Ni on the O-columns is challenging, the results indicate the presence of a foreign species on the columns which may be Ni. The first component can be interpreted as O-columns with a high number of oxygen vacancies generated due to the reducing environment.

Conclusion
A semi-quantitative approach utilizing the open-source packages abTEM and Atomap was adopted to identify the defect position of Ni in A-site deficient La-doped $SrTiO_3$ upon exsolution under reducing atmospheres. Simulated multislice images show a linear Z-dependency for the experimental conditions used. The intensity distribution of the O-columns in the experimental ABF image is best modelled using three Gaussians. The component of highest intensities holds a relative mean value to the main component that agrees with a calculated intensity ratio for the presence of Ni using linear Z-dependency. The interstitial defect position of Ni is expected to play an important role in the diffusion step of the exsolution process.

Poster Group 2

Scanning transmission electron microscopy (STEM) is a technique consisting in the illumination of a specimen with a convergent beam of electrons. Through the recording of the far-field intensity pattern generated for a variety of scan points, it is then possible to track specimen-induced changes in the position-dependent momentum distribution of the electrons. Such momentum redistributions are the result of the subtle interplay of repeated elastic and inelastic scattering events occurring throughout the propagation of the electron wave within matter, which leads to the appearance of both thickness-dependent Bragg reflections and diffuse backgrounds, including thermal. Such scattering can generally be understood as characteristic of the high-frequency components of the interaction, being then useful for atomically resolved investigations of crystals. Conventional examples of those include the high-angle annular dark field (HAADF) imaging mode, comprising in large part of thermal diffuse scattering (TDS), and the center of mass (CoM) of the far-field pattern, which informs on the gradient of the electrostatic atomic potential of the specimen [1]. In addition to those high-frequency sources of contrast, the CoM signal is sensitive to long-range features, such as the Lorentz interaction with stray and internal electromagnetic fields [2] or the influence of the shape envelope of the specimen [3,4], which can otherwise be thought of as a refraction effect along the optical path of the electrons.

In this work, we make use of the microprobe set-up of the microscope, where the semi-convergence angle α is kept equal to a few mrad at most, to investigate the long-range sources of contrast in a CoM-STEM image. In this condition, the numerical aperture remains small enough to not include the high-frequency components (i.e. the probe is larger than inter-atomic distances), and lower frequencies become dominant. As is confirmed here, this strategy still does not permit a full elimination of diffraction effects in the result, since repeated scattering makes it possible for electrons to be scattered back to the central beam. As a result, electrons with a large variety of path length within the specimen end up contributing to the result, which then creates a dependence of the apparent long-range contrast to the underlying atomic lattice, i.e. low- and high-frequencies are not independent anymore. This effect nevertheless only accounts for a small fraction of the CoM signal extracted, and a low value of α indeed permits a direct visualization of particle shape in momentum-resolved STEM.

Moreover, we introduce a simplified quantitative STEM simulation approach where the specimen potential is modeled as a continuous shape envelope function, thus with no atomic structure at all, multiplied by a known mean inner potential. Such an approach permits a major acceleration of the

calculations needed to computationally reproduce an electron microscopy measurement, thanks to the lower pixelization of the simulation window, and can then be used for a semi-quantitative analysis of long-range contrast. Here, the results provided by the continuous object simulation method are compared to those based on an atomistic specimen, as well as to experiments, for further confirmation of the dominance of shape effects in a CoM image. By additionally including electromagnetic fields in the model, it becomes achievable to reproduce this supplementary source of contrast in (S)TEM images, for instance in the cases of electron holography or differential phase contrast [5]. What makes this prospect particularly interesting is that, even now, most of the analysis done in the framework of those methods still rely on the phase object or weak phase object approximations, and thus do not include the influence of propagation.

The present work is performed on the basis of experimental data collected from Au nanoparticles as well as large amorphous latex spheres. Data analysis is supplemented with an extensive multislice simulation study, including with the newly introduced continuous object model, which is also used to explore further material cases and future prospects.

Figure 1: Comparison between experimental (left) and simulated (right) CoM-STEM micrographs of Au facetted nanoparticles. The vectorial quantity is depicted using a colour wheel representation, with the brightness representing the modulus and the hue the orientation. The simulation shows qualitative agreement with the experimental data within the marked region of interest (white doted square). The model used for the atomistic multislice simulation is visible in the bottom right corner of the figure.

PS-09, Lecture Theater 2, august 26, 2024, 14:00 - 16:00

Background incl. aims
Copper rich sulfides have attracted significant attention in the last few years as potential thermoelectric materials. These materials exhibit a rich microstructure with the existence of order/disorder domains or coexistence of different crystallographic phases, which plays a crucial role on the thermoelectric properties of copper-based sulfides. In here, the case study of a Cu2.3Mn0.7GeS4 nanocomposite is reported. It is characterized by two different phases (enargite and stannite), which form interconnected domains at the nanoscale. By means of scanning electron diffraction tomography, our aim is to accurately characterize the crystal structure of the nano-sized different domains with a single data acquisition.

Methods
As a first reported example, Scanning Precession Electron Tomography (SPET) is presented here as a tool to characterize ab initio more than one region of interest (ROI) with a single acquisition. Eggeman et al. exploited a similar approach for analyzing the volume and orientation of domains in crystalline Ni-based superalloys. This technique combines a scanning procedure with the already widely used Precession-assisted Electron Diffraction Tomography (PEDT) routine, avoiding the need of an accurate tracking system. The area of interest is selected, and the electron beam is scanned across it with the desired step size while collecting the diffraction patterns. Afterwards, the sample is tilted and the scanning procedure is performed again and so on, obtaining this way a tomography of a 2D space. SPET was performed with a Jeol F200 on the nanocomposite cut by FIB in a TEM lamella. We also tested the feasibility of this approach on a TESCAN TENSOR analytical 4D-STEM to similarly acquire diffraction tilt series on different ROIs of the sample under test.

Results
From the SPET measurements made on the Jeol F200, we show how it is possible, by appropriately sort the acquired diffraction patterns, to perform structure solution and refinements of more than one nanodomain at the same time. This also allows to compare in a reliable way the obtained structures, being the experimental conditions equivalent. In this case, the sorting was performed with NMF (Non-negative Matrix Factorization).
On the TESCAN TENSOR, the acquisitions were performed with a parallel beam at different tilt angles on a ROI using a large grid. 3D ED tilt series were then extracted and used for a structure refinement of the two phases (Fig. 1). Secondly, using a fine grid at a single tilt angle, precession-assisted 4D-STEM was used to determine the distribution of enargite and stannite, including their orientations, in the same ROI. This identification is based on templates matching generated directly from the actual crystal structure identified by 3D ED.

Conclusion

These results illustrate how these electron diffraction tomography approaches can allow us to better understand the internal structure of this type of nanocomposites and to establish a link between their physical properties and their (micro-)structure, allowing this way to customize them for obtaining the desired performances.

These results were obtained as part of the European project NanED (Electron Nanocrystallography – H2020-MSCA-ITN GA956099).

TEM Exploration of High-Performance Non-Noble Metal Catalysts for OER

David Llorens Rauret[1], Mr. Ranit Ram[2], Dr. F. Pelayo García de Arquer[2], Dr. Alba Garzón Manjón[1], Prof. Jordi Arbiol[1,3]
[1]ICN2, CSIC and BIST, Bellaterra (Barcelona), Spain, [2]ICFO and BIST, Castelldefels (Barcelona), Spain, [3]ICREA, Barcelona (Barcelona), Spain

PS-05 (3), Lecture Theater 3, august 30, 2024, 10:30 - 12:30

Within the current global energy crisis scenario, the oxygen evolution reaction (OER) has emerged as a pivotal process in vital systems for sustainable energy generation, conversion and storage. However, the demanding 4-electron transfer mechanism of the reaction requires exceptionally high activity levels, currently only achieved by noble metal-based nanocatalysts (1). This limitation impedes the widespread economic adoption of OER systems, restraining advancements in green energy technologies. Consequently, recent research has focused on non-noble metal-based systems such as cobalt tungstate ($CoWO_4$). $CoWO_4$ has emerged as promising and cost-effective noble metal-free catalyst for OER, thanks to its remarkable physicochemical properties (2). Nevertheless, a profound up to the atomic scale comprehension of the catalytic system's structure, underlying reaction mechanisms, and potential degradation and alterations in composition and morphology under harsh OER conditions, requires the use of powerful and sophisticated characterization tools (3).

In that regard, (scanning) transmission electron microscopy ((S)TEM) stands out as an outstanding solution, integrating high spatial resolution imaging with spectroscopy techniques for chemical analysis. Moreover, TEM can be adapted for in-situ experiments, allowing the direct observation of dynamical effects in catalytic systems within their natural or operational environment. Furthermore, additional synchrotron X-ray absorption spectroscopy (XAS) served as a powerful complement to the comprehensive (S)TEM characterization.

In this work, (S)TEM was employed to effectively examine the catalyst's structural and compositional changes during activation, such as the formation of vacancies on its surface. These vacancies are crucial contributors to the observed high activity and stability of the system (4). The results yielded unique information about the catalyst's morphology, which would have been inaccessible through other methods. Furthermore, employing in-situ TEM allowed for initial observations of the catalyst's response to electrochemical bias. Finally, XAS helped to establish a cohesive correlation with the insights gained from TEM analysis.

In summary, the exploration of highly active catalysts for the OER not only unlocks valuable insights into catalyst activity and stability but also correlates it to the system's morphology and composition. This structure-property relationship is crucial for advancing the development of catalytic materials with exceptional efficiency and enduring stability in OER applications, contributing significantly to the progress of cost-effective green energy technologies.

Poster Group 2

1. Introduction/Background
The tooth, mainly composed of dentin, which lies between enamel and pulp, is the hardest organ in the human body. Dentin is a mineralized collagen framework comprising 70% carbonated hydroxyapatite, 20% organic matrix (mainly type I collagen forming collagen fibrils), and 10% water. The tooth's necessary mechanical resistance without causing it to fracture comes from its particularly complex micro- and nano-structural organizations. Dentinogenesis Imperfecta (DI) is a rare genetic disease that causes severe dentin hypomineralization and damage to its structure (de la Dure-Molla, 2015). In some cases, DI is caused by a type I collagen mutation (Yamaguti PM, 2023), which leads to the modification of dentinal tissue organization at the nanoscale and microscale. Clinically, it can lead to rapid attrition of the dentin tissue, eventually leading to tooth loss, probably due to lower mechanical properties. In this study, we present an original analysis of the nanostructure of the healthy dentin compared to dentin affected by DI. A focus on collagen fibrils and hydroxyapatite entanglement in both samples has been performed from transmission electron microscopy (TEM) techniques.
2. Methods
Both permanent and deciduous teeth with no visible pathological signs were prepared for the control samples. In contrast, a deciduous molar was chosen for pathological dentin from a patient diagnosed with DI exhibiting damage to type I collagen. All samples were sectioned from the crown to the root and mechanically polished using abrasive Si-C paper with decreasing grain size. The samples were then dehydrated progressively through a series of increasing ethanol concentrations. TEM samples were then prepared in the different samples at different location in teeth by using a FEI ThermoFisher Helios Nanolab 660 focused ion beam. The obtained sections were observed with a FEI ThermoFisher TITAN3 G2 80-300 transmission electron microscope equipped with a Cs probe corrector given a 0.07nm spatial resolution and a SuperX detector for energy dispersive X-rays spectroscopy (EDX) analyses.
3. Results
Using HR-(S)TEM techniques, the microstructure of the healthy dentin has been studied at different scale close the enamel and in the middle dentin. Collagen fibrils and hydroxyapatite crystals are completely tangled. While fibrils looks like long cylinders with sizes over than hundreds of nanometers, crystals are usually smaller than 5 nm in length and it seems that they are roughly aligned with the direction of collagen fibrils.
Let’s first focus on collagen fibrils. The analysis of their diameter revealed that collagen fibrils tends to shrink as they are close to the enamel. Their distribution in the intertubular dentin also appears to be different close the enamel and in the middle dentin. The collagen fibrils are organized in a more isotropic way near enamel than in middle dentin where they are lying in planes perpendicular to the tubule axis. In those planes perpendicular to tubule axis, bundles of collagen fibrils and mineral are oriented in preferential directions, creating a woven structure.

Concerning the hydroxyapatite crystals, we observed that they are organized in S-shaped structure composed of individual HAP crystals and parallel to the adjacent fibrils. The individual crystals are mainly elongated along their c-axis but can also be elongated along a- and b- axis. This organization looks similar regardless of the location in the dentin.
In comparison, DI dentin look very different. The density of collagen fibrils drastically drops compared to the one in the healthy dentin. At the opposite, hydroxyapatite crystals are much denses and their distribution looks homogeneous. Looking at individual crystals' size, we did not observe any statistical difference between healthy dentin and dentin affected by DI. With the EDS analysis, we found Ca/P ratios approximatively at 1.67 (ideal hypothetical value in hydroxyapatite crystals), with a tendency to lower values in dentin affected by dentinogenesis.
4. Conclusions
At the nanoscale, dentin shows a complex and anisotropic organization involving a mineral phase made of hydroxyapatite crystals and an organic phase mainly made of collagen fibrils. In this work, we firstly analyzed precisely the microstructure of dentin according to the location in the tooth and with cross-sections parallel or perpendicular to the tubular paths thanks to the combination of FIB and TEM. The comparison of the healthy dentin and the DI one brings new insight into the tooth formation.

Poster Group 1

Background incl. aims
Local hyperinnervation plays a pivotal, yet poorly understood role in the initiation and maintenance of atrial fibrillation (AF). Changes in the intricate 3-dimensional (3D) network of nerves are difficult to characterize using traditional histological methods and AF has been challenging to study in preclinical rodent models. Non-destructive imaging techniques capable of visualizing larger tissue samples from large animal models are crucial to understand innervation changes in AF. Here, we aimed to investigate the feasibility of 3D light sheet fluorescence microscopy (LSFM) in equine atrial tissue and characterize the autonomic cardiac remodeling in a horse model of experimentally induced chronic AF.
Methods
Biopsies from the anterior descending ganglionated plexus were harvested from horses after 4-months of induced AF (n = 9), from horses with naturally occurring AF (n = 3) and healthy control horses (n = 3). Immunostaining with two neuronal markers (Tyrosine hydroxylase and Neurofilament) in parallel with a vascular marker (Transgelin) was performed to determine the local density of nerves and vasculature by computational image analysis. Whole-mount immunohistochemistry and clearing was optimized for equine heart samples by testing different depigmentation, permeabilization and imaging protocols.
Results
We present a protocol for 3D imaging of nerves in large equine atrial samples, spanning several centimeters in size. Optimized sample preparation with stepwise chemical and enzymatic extracellular matrix loosening and digestion enabled uniform sample labelling with antibodies against neuronal markers. Customized autofluorescence bleaching, sample clearing and imaging parameters facilitated high resolution imaging of cardiac innervation across the entire tissue sample. Computational analysis of atrial innervation permitted quantitative analysis in the study groups to demonstrate spatial changes occurring in atrial fibrillation.
Conclusion
3D LSFM in large animal models can improve our understanding of the mechanisms of diseases. This newly developed sample preparation protocol is well suited for single-cell resolution imaging in dense cardiac biopsies. We show the applicability of the method in characterizing innervation changes in an equine model of AF.

Operando structural and chemical imaging of lithium battery interfaces

Sayantan Sharma[1,2], Dr. Luca Cressa[1], Dr. Tom Wirtz[1], Dr. Santhana Eswara[1]
[1]Advanced Instrumentation for Nano-Analytics (AINA), Materials Research and Technology Department, Luxembourg Institute of Science and Technology (LIST), Belvaux, Luxembourg,
[2]University of Luxembourg, Belval, Luxembourg

PS-04 (2), Plenary, august 26, 2024, 14:00 - 16:00

Background incl. aims
Lithium metal is a very promising anode material to develop batteries with higher energy density due to its high specific capacity and low redox potential. However, the widespread use of lithium as anode is hindered by the safety concerns stemming from the formation of dendritic structures at the electrode-electrolyte interfaces during battery operation [1]. Hence, understanding the fundamental mechanism behind the formation of these dendritic structures is crucial for the utilization of lithium metal in producing batteries with enhanced energy density and safety. Traditional ex-situ and in-situ analysis techniques are not sufficient to understand the transient processes involved in the nucleation and growth of these dendrites. Thus, operando techniques, which allow analysis while the battery is functioning, are essential for gaining deeper insights. The primary aim of this study is to devise a methodology for capturing the nanoscale structural and chemical changes occurring at the electrode-electrolyte interface during battery operation.
Methods
Our approach utilizes a dual-beam focused ion beam-scanning electron microscope (FIB-SEM) equipped with an in-house developed magnetic sector secondary ion mass spectrometer (SIMS) for operando structural and chemical imaging [2]. Secondary electron (SE) imaging helps to visualize the structural changes and SIMS imaging depicts the chemical alterations at the battery interfaces. Here SIMS is used as it is an ideally suited technique for high-sensitivity chemical analysis and imaging of all elements, including light elements like lithium. Thus, SIMS enables unequivocal detection of the lithium rich dendrites near battery interfaces. A special operando analysis setup has been developed through which the charging-discharging of the battery can be performed inside the FIB-SEM-SIMS instrument using an external potentiostat, while maintaining the necessary sample bias conditions to allow secondary ion extraction for simultaneous SIMS analysis.
Results
Using the FIB-SEM-SIMS instrument, all solid-state symmetrical lithium cells with garnet type solid electrolyte lithium lanthanum zirconium oxide (LLZO) were analyzed both before electrochemical cycling and after short-circuit [3]. Phases with darker contrast were identified in the gallium ion induced SE images of the electrolyte after short-circuit failure, SIMS imaging showed higher lithium-ion signal in those phases (Fig. 1e,1f). Thus, the presence of lithium rich dendrites in LLZO after short-circuit was confirmed by SIMS. The development of the operando setup enables us to perform SE and SIMS imaging of the battery interfaces during cycling. Therefore, it is now possible to detect and image the progression of lithium dendrite growth at different stages of cell operation. Furthermore, this operando setup allows direct correlation between the alterations in structure and chemistry of the electrode-electrolyte interface with the evolution of interfacial resistance by combining electrochemical experiments such as impedance spectroscopy with the SEM-SIMS analysis.
Conclusion
In summary, our operando FIB-SEM-SIMS setup allows real-time observation of the nanoscale processes at the interfaces linked with dendrite growth in solid-state lithium metal batteries. This

helps in acquiring a more complete understanding about the phenomenon of dendrite formation in lithium metal batteries, paving the way for development of batteries with improved safety as well as electrochemical performance.

High Spatio-Temporal Resolution Differential Phase Contrast Imaging via Detector Signal Digitisation

Julie Marie Bekkevold[1,2], Dr. Jonathan J. P. Peters[1,2], Prof. Ryo Ishikawa[3], Prof. Lewys Jones[1,2]
[1]School of Physics, Trinity College Dublin, Dublin, Ireland, [2]Advanced Microscopy Laboratory, Dublin, Ireland, [3]University of Tokyo, Bunkyo, Tokyo, Japan

Poster Group 2

Imaging of the functional properties of materials using phase contrast techniques is increasingly in-demand. The high sensitivity of phase techniques to weak phase objects makes them excellently equipped to study weakly scattering and beam sensitive materials in STEM. To study beam sensitive materials, the beam current must be significantly reduced to avoid damaging the sample. However, this often means that high dwell times are used to collect a high enough signal for the image to be interpretable. This requires the sample to be stable and unchanging over the significant time needed to acquire the frame. A different approach to collect enough signal is acquiring many subsequent frames as a lower dwell time and then later average the signal to get the final interpretable image. This has the added benefit that it fractionises the dose resulting in lower beam damage to the sample[1]. However, at fast scan speeds a scintillator detector is often too slow to keep up, resulting in streaking artefacts in the image due to single electron events lasting longer than the pixel dwell time[2].
In this work we investigate the practicability of in-hardware digitisation of scintillator detector signal in the ABF region for differential phase contrast (DPC). Digitisation retains the precision of electron detection events in time, such that every electron is detected in the correct pixel only[3]. Still, the occurrence of two electrons too close in time to be separated into two digitised events increases at collection angles within the semi-convergence angle because the arrival rate of electrons to the detector is high. This coincidence loss problem reduces the practicable beam current for digitisation imaging in the ABF region. Using segmented detectors for DPC imaging reduces the coincidence loss, since each segment is digitised separately.
Experimentally using live digitisation of four segments from an annular segmented detector, we demonstrate that atomic position precision can be retained at incredibly high scan speeds. With a low beam current of 5.2pA, to reduce loss of signal due to coincidence loss, and multi-frame imaging, the atomic column positions in an STO sample have been recorded at dwell time as low as 50 ns. The analog images captured with the same parameters show significant loss of information in the fast scan direction due to image streaking. At this high-speed scanning, binning of the multi-frame data stacks allow us to gain time-resolution as well. Thus, we may sacrifice some of our spatial resolution for time-resolution – paving the way for in-situ materials characterisation with DPC.

Visualising microstructural dynamics of titanium aluminium nitride coatings under variable-temperature oxidation

Dr Ofentse Makgae[1], Dr Filip Lenrick[2], Dr Volodymyr Bushlya[2], Dr Jon Andersson[3], Dr Rachid M'Saoubi[3], Martin Ek[1]
[1]Centre for Analysis and Synthesis, Lund University, Lund, Sweden, [2]Division of Production and Materials Engineering, Lund University, Lund, Sweden, [3]R&D Materials and Technology Development, Seco Tools AB, Fagersta, Sweden

PS-09, Lecture Theater 2, august 26, 2024, 14:00 - 16:00

Background incl. aims
Titanium-aluminium nitride (Ti1-xAlxN) coatings are used to achieve high oxidation and wear resilience in coated metal cutting tools. For the highest performance, the coatings' composition and microstructure are carefully controlled. However, it is difficult to obtain knowledge how these factors effect of the oxidation processes at the microstructural level because studies are most commonly performed: (1) post mortem and cannot observe the structural dynamics underlying the oxide formation in real-time; or (2) averaged over a large volume of the sample (and use powdered materials rather than actual coatings) and lack the spatial resolution to form connections to microstructure. Here, we describe the use of ETEM for visualizing the oxidation process at high spatial and temporal resolution, using technically relevant materials, to provide important insight into where oxidation initiates and how it proceeds to determine the performance of the coating.[1]

Methods
Industrial style Ti1-xAlxN coatings were grown on WC-Co substrates with x = 0, 0.18, 0.44, & 0.67. Samples were prepared through focused ion beam milling (fig. 1a), transferred to MEMS heating chips (Norcada Inc., fig 1b), and finally imaged in ETEM (Hitachi HF3300-S, operated at 300 kV) during heating in an O2 environment (ca. 1 Pa). The samples were observed over a temperature range from 200 to 1000 °C and energy dispersive X-ray spectroscopy (EDX) with pre- and post- elemental mapping by EDX.

Results
The high-frame-rate ETEM movies show that oxidation in TiN proceeds at the grain boundaries and cracks formed during the heating process; in contrast, Ti1-xAlxN coatings transform from large as-deposited grains into oxide nanoparticles. The onset temperature increase with increasing Al content up to x= 0.44, as shown in fig. 1c-s. Moreover, high-resolution ETEM imaging show the presence of anatase TiO2 at the early stages of oxidation across all compositions. Above ~850 °C, the oxide nanoparticles grow through crystal merging, diffusion and recrystallization to form rutile TiO2. The EDX elemental maps coupled with secondary electron imaging reveal a uniform TiO2 sublayer decorated with increasing coverage of Al2O3 particles for x = 0.18 to 0.44. In contrast, coatings with x = 0.67 reveal a complete in-plane phase separation of Al- and Ti-oxides.[1]

Conclusion
The trend with increasing onset temperature for the oxidation with increasing Al content is consistent with the resilience of the corresponding coatings during cutting operations. The in-plane separation observed for the highest Al content (x = 0.67) exposes the softer TiO2 at the surface, and the TiO2-Al2O3 grain boundaries can act as a conduit for oxygen to reach further into the coating;

together, these results can rationalise the poorer long-term oxidation resilience resulting from excessive Al.[1] Finally, the study provides insight into the real-time structural dynamics underpinning the oxidation resistance of Ti1-xAlxN coatings, illustrating how ETEM can uniquely complement other in situ techniques that have recently been applied to these materials.[2,3]

Advanced EELS spectroscopy characterization of AlGaN/GaN materials

Mr Esteve Drouillas[1,2], Mrs. Bénédicte Warot-Fonrose[2], Mr. Jean-Gabriel Mattei[1]
[1]STMicroelectronics Crolles 2, Crolles, FRANCE, [2]CEMES-CNRS, Toulouse, FRANCE

PS-03 (1), Lecture Theater 2, august 29, 2024, 14:00 - 16:00

Background incl. aims
The combination of STEM with electron energy-loss spectroscopy (EELS) and Electron-Loss Near-Edge Structure (ELNES) has gained great interest in the microelectronics industry. Indeed, ELNES can provide additional information on local atomic and electronic structures of materials compared to the already commonly used XEDS method for chemical quantification. This project intends to investigate High-Electron Mobility Transistor (HEMT) devices based on AlxGa(1-x)N semiconductors for high-power and high-frequency applications.
Methods
The HEMT device presented in this work [See Fig.1 (a) and (b)] is composed of a GaN channel and an AlGaN barrier structure separated by a few-nanometer AlN spacer grown to improve the performance of the 2-Dimensional Electron Gas (2DEG) formed at the interface [2]. The wider bandgap and stronger polarization of AlN compared to AlGaN provides higher breakdown fields and enhances the electron mobility and sheet density in the 2DEG while limiting alloy scattering. Due to significant lattice mismatch between GaN and Si, an AlN nucleation layer is grown first on 300 mm Si wafers. Successive AlxGa(1-x)N buffer layers with decreasing amounts of Al are then needed to accommodate stress in the structure. This buffer stack allows the growth of an ideally crack-free GaN channel as shown in Fig. 1 (a), assuring optimal electron mobility in the device. Layers are grown using MOCVD deposition method on Si (111) wafers. The main goal of this project is to investigate the comportment of materials in this device, especially at the active AlGaN/AlN/GaN interface through EELS analysis with “ultimate” resolution. TEM experiments are performed on a probe Cs-corrected JEOL Neo-ARM 200F equipped with a Cold-FEG and a GIF (Gatan Image Filter) Continuum spectrometer.
Results
Preliminary work has been conducted to investigate the variation of the plasmon peak in the low-loss region (≈ 10-30 eV) along the buffer stack which demonstrated a linear dependency between the plasmon energy peak (Ep), and the fraction of Al in the ternary alloys, xAl [Fig. 2 (a)]. Likewise, the acquisition of the N K-edge ELNES structure along the buffer layer stack has been conducted at 200 kV, highlighting the transition between layers [Fig.2 (b)]. The most significant difference is observed for the first 3 peaks of the spectra (≈ 400-410 eV) where the first and third peaks gradually gain in intensity over the second as the AlN mole fraction increases in the ternary alloys. According to literature [3], these peaks should result from N-cation anti-bonding interactions and the intensity re-distributions is mostly due to the valence d-electrons of the GaN. These experimental N K-edges are consistent with calculated wurtzite AlxGa(1-x)N spectra obtained in the previous studies [4,5].
Conclusion
Based on these first results, additional work has been carried out to optimize TEM sample preparation for EELS analysis, especially using Plasma-FIB Xe and PIPS II Ar ion polishing to successfully prevent Ga implantation experienced with standard Ga FIB thinning as illustrated by Fig.3 (a) and (b). Further experiments will be performed to investigate electron beam irradiation as well as the contribution of lower acceleration voltage (i.e. 80 and 60 kV) on the N K-edge ELNES analysis.

PS-05 (2), Lecture Theater 1, august 28, 2024, 14:00 - 16:00

Background incl. aims
Oxide materials play an important role in heterogeneous catalysis, either as functional nanomaterials in their own rights or as supports for other active nanostructures. The reactivity of oxide materials is often attributed to oxygen deficient surface sites. However, the surface motifs can undergo substantial rearrangements that are difficult to predict. A prototypical example of such complex behaviour is VOx/TiO2 catalysts, which are widely used for e.g. selective catalytic reduction (SCR) of NOx emissions. VOx undergoes a redox cycle during the SCR reaction [1], where the possible effect of the supporting TiO2 surface has been much debated. The debate reflects that earlier investigations have not provided definite information on local variations in structure and oxidation state of VOx under catalytic reaction conditions. To overcome this challenge, we present in situ atomic-resolution electron microscopy and spectroscopy observations of VOx/TiO2 catalysts under reducing and oxidizing reactions conditions.

Methods
The investigations focus on a VOx/TiO2 catalyst prepared by impregnation of commercially available TiO2 nanoparticles [2]. The morphology of a single catalyst particle is shown in Figure 1a. The catalyst was investigated using a Titan ETEM instrument [3]. High-resolution transmission electron microscopy (HRTEM) and electron energy loss spectroscopy (EELS) data, for structural and oxidation state analysis respectively, were recorded using low-dose-rate approaches [2,3]. The oxidation states were measured both as an average over multiple particles [2] and locally at individual facets by means of scanning TEM (STEM) [4].

Results
The integrated oxidation state of the VOx/TiO2 catalyst could be reversibly tuned in situ through the V(V)-V(II) range by suitable choice of gaseous environment. For conditions relevant to the SCR reaction (excess O2 with traces of NH3 and NO) an average oxidation state between V(V) and V(IV) was measured, consistent with operando spectroscopic and theoretical investigations [1]. However, the STEM-EELS measurements illustrated in Figure 1b,c revealed that the {001} facets retained oxidation states closer to V(V), whereas {101} facets on the same nanoparticle were almost fully reduced to V(IV). This difference rationalizes previous suggestions of enhanced reactivity for the {001} facets. The difference was consistently found for all nanoparticles investigated [4].

Increasing the reducing potential of the gaseous environment further revealed also reversible structural alterations in the outermost atomic layers of the VOx/TiO2 catalyst; the VOx surface transformed from an ordered to a disordered state concomitant with a reduction to the V(IV)-V(III) range in response to oxygen exchange at the surface. Surprisingly, the restructuring was found to depend on the supporting facet, with {001} facets demonstrating a greater ability to accommodate

large changes in oxidation state through its high surface cation mobility, as shown by the changing contrast at the marked atomic columns in Figure 1d [2]. The high-index {10l} showed even more extensive restructuring, forming rock-salt VO with V(II); this localized highly reduced phase must be accounted for to understand the overall redox behaviour of the supported VOx.[5]

Conclusion

The enhanced reactivity of the (001) facet terminations of anatase TiO2 have been extensively studied for photocatalytic reactions. Whether such properties extend to VOx/TiO2 catalysts, e.g. in relation to low temperature NH3-SCR of NO is addressed here for the first time at the atomic level. Varying cation coordination and density were found to be important factors for explaining differences between facets. This work shows that ETEM/STEM/EELS can be used as a unique tool to discriminate between different structural motifs at the atomic level, even on commercial catalysts.

Poster Group 2

Background incl. aims:
The properties of polymeric materials, such as their strength, flexibility, and durability, are deeply influenced by their crystalline structure. Understanding this structure at a microscopic level is crucial for the fabrication of materials with specific properties for various applications. High-resolution transmission electron microscopy (HRTEM) is a powerful tool for visualizing the arrangement of polymer chains and crystalline regions within polymeric materials. However, due to the sensitive nature of polymers to electron beams, achieving high-resolution images for insights into polymer polymorphism without damaging the sample has been a challenge.

Methods:
In our research, we tackled this challenge by employing a technique called low-dose focal series reconstruction (LD-FSR)[1] to conduct high-resolution TEM imaging of thin films of polycaprolactone (PCL), a commonly used biodegradable polymer. LD-FSR allowed us to capture detailed images of polymer crystals with sub-molecular resolution while minimizing damage to the sample caused by the electron beam. Additionally, we utilized scanning nanobeam electron diffraction (NBED) with the 4D scanning transmission electron microscopy (STEM) technique to map the crystalline domains at both micro- and nano-scales[2] within the PCL samples. Furthermore, to broaden our understanding of polymer polymorphism, we investigated Langmuir–Blodgett thin films[3] of another polymer with multiple crystalline phases, polyvinylidene fluoride (PVDF).

Results:
Employing LD-FSR combined with 4D STEM, we directly observed interacting polymer chains in the crystal lattice, elucidating the crystal structure with a high degree of precision, including lattice deformations in PCL. In addition, by using 4D STEM in conjunction with nano Fourier-transform infrared spectroscopy (nano-FTIR) we were able to identify the presence of a partially crystalline phase alongside the well-known α-PVDF crystal phase. These findings, supported by bulk measurements such as FTIR and X-ray diffraction (XRD), and other techniques like scanning electron microscopy (SEM) and atomic force microscopy (AFM), represent a significant advancement in our understanding of PVDF polymorphism.

Conclusions:
Our combined real space imaging and nano-diffraction approach provides a unique opportunity to investigate nanoscale polymer crystallinity with high resolution, revealing distortions in the polymer structure on the local scale. Similarly, it allows for the identification of new polymeric phases based

on previously imaged different morphologies. Our methodology represents a powerful tool for the structural science of polymers in view of complex and variable polymer crystallinity, resulting from differences in preparation and processing.

Three-dimensional classification of dislocations from single projections

Dr. Tore Niermann[1], Ms. Laura Niermann[1], Mr. Michael Lehmann[1]
[1]Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany

Poster Group 2

Background incl. aims
Many material properties are governed by dislocations and their interactions. Examples range from the strengthening of metals and alloys to efficiency in semiconductor laser devices. Thus, knowledge of the three-dimensional topology of dislocation networks is crucial for material engineering. A two-dimensional projection of dislocation networks can be readily obtained by conventional (scanning-) transmission electron microscopy (S/TEM) images. Here we show a way to reveal the three-dimensional location of dislocations and simultaneously classify their type from a single 4D-STEM measurement [1].
Methods
Under systematic row conditions, where the systematic row is oriented non-parallel to the dislocation's Burgers vector, the 4D-STEM dataset can be represented by a reduced 2D dataset, with a spatial dimension x perpendicular to the dislocation line and a diffraction dimension q in the direction of the systematic row. Due to dynamical diffraction effects, such (x, q)-datasets exhibit sufficient information to uniquely identify the dislocation type and its three-dimensional depth within the S/TEM lamella. This identification is facilitated by comparison of the experimental (x, q)-data to a database with calculated (x, q)-data, where the relevant parameters Burger's vector, dislocation depth, lamella thickness, and beam tilt were varied. The column approximation is sufficiently accurate for the calculation task, which allows a numerically efficient calculation of the database by a forward propagation of the Darwin-Howie-Whelan equations [2].
Results
For an exemplary dislocation the results are shown in the figure. The investigated dislocation is a threading screw dislocation with a line vector of [0001] found within a GaN buffer grown on a sapphire substrate. The data was obtained under (0002) systematic row conditions. In the left-hand panel the experimentally obtained (x, q)-data for this dislocation is displayed. The panel in the middle shows the best matching calculation for the data, which was obtained for a Burgers vector of [000-1], a lamella thickness of 132 nm, and a depth of the dislocation core of 55 nm behind the entrance surface. The right-hand panel shows the mean squared error evaluated during the comparison, which is the average squared difference between the experimental data and the individual (x, q)-data from the database. Even though local minima are found for several specimen thicknesses and dislocation depths, the global minimum can be easily identified.
Conclusion
The ability to three-dimensionally locate a dislocation within a specimen and simultaneously classify its type provides an extremely powerful way for the investigation of dislocation networks. A 3D classification is possible from a single 4D-STEM measurement within the limitations of the g·b criterion. In comparison to tomographic methods a single 4D-STEM measurement can be performed much faster and with less dose, which enables the investigation of dislocation networks in beam-sensitive materials or in dynamic conditions, like during an in-situ heating/cooling experiment.

Microstructural evolution of zeolitic nanocrystals for CO2 capture by Environmental in-situ TEM

Dr. Simona Moldovan[1], Mr Edwin Clathworthy[2], Mrs. Kalthoum Nakouri[3], Mrs. Svetlana Mintova[2]
[1]CNRS, Rouen University, Groupe de Physique des Materiaux, Rouen, France, [2]Normandie University, ENSICAEN, Laboratoire de Catalyse et Spectrochimie, Caen, France, [3]TOTALEnergies, Solaize, France
PS-05 (3), Lecture Theater 3, august 30, 2024, 10:30 - 12:30

In the current context of demographic evolution resulting in the considerable increase in greenhouse gas emissions, the academic and industrial community allocates more and more resources to the development of new solutions for capturing, storage and recovery of these undesirable products, the main component of which is carbon dioxide (CO2). Micronsized zeolites such as FAU, LTA or TiSi are currently the most widely used for CO2/CH4 separation, but they have disadvantages such as reduced accessibility of pore volume, slow CO2 kinetics, low regeneration and low cycling, and high costs of organic templates used for their synthesis. In this context, functionalized nanosized zeolites (RHO type) with fully accessible active internal and external surfaces and high crystalline yields were synthesized [1]. Considering the ultimate atomic resolutions (<1 Å) achieved in a TEM, and the in-situ capabilities available nowadays, the in-situ environmental TEM is the only approach able to allow the real-time exploration of the impact of specific parameters such as the gas flow, pressure, temperature on the nanosized crystals evolution upon reactions. It allows the real-time analysis of parameters such as crystal size, the proportion of open/closed pores and/or crystalline facets.
In this study, we focus on and the microstructural changes of nanosized RHO zeolites analyzed by the MET in-situ Environmental under a CO2 flux under high temperatures and pressures.

The STEM-HAADF 2D and 3D observations were carried out on a double corrected Analythical JeolARM 200CF equipped with a Jeol Centurio EDS detector and a Quantum GIF. The in-situ experiments were performed by using an Environmental-Cell from Protochips [2] which has been employed under 1 bar of CO2 flow and for temperature increased from 25 to 900 °C with a heating rate of 10 °C/min. Owing to the high sensitivity of zeolites upon electrons irradiation, the STEM observations were carried out at well-defined temperatures (the beam was turned off during the heating steps).

The RHO nanozeolite was initially heated under Ar at 200 °C, and images under these conditions were taken as references. Maintaining the temperature at 200 °C, CO2 was then contacted with the sample followed by heating and imaging at 700°C, 800 °C and 900 °C. No significant lattice expansion occurs between 200 and 700 °C, when the RHO nanosized zeolite is exposed to CO2. However, the visible expansion of the crystals at 800 °C is consistent with the structural flexibility behavior under air where we observed a substantial increase of the lattice parameter (0.2221 Å) from 700 to 800 °C due to the change in symmetry of the crystalline structure from non-centrosymmetric to centrosymmetric [1]. Superposition of the very same nanozeolite crystals recorded at different temperatures revealed distinct differences in the size of the discrete nanocrystallites. Specifically, the images recorded at 800 °C [3] and 900 °C superimposed with the reference images taken at 200 °C under CO2 show a clear difference in the size of the nanosized crystals, corresponding to an expansion of the particle-matrix by 3 nm and 4.8 nm, or 9% and 15% of the average particle size, respectively. The increase in the volume of RHO crystals was evaluated on the basis of 2D micrographs and corroborated with the exploration of the volume of nanocrystals obtained by

electron tomography. The particle expansion between 800°C and 900°C is accompanied by a sharp change of the nanocrystal's microstructure. The crystals morphology remains stable up to 1000°C. This original study highlights for the first time the flexibility and the microstructural stability of RHO nanosized zeolite at high temperatures under CO2 exposure by in situ HRTEM.

Unsupervised Deep Learning approach for image registration in Correlative Microscopy for the localization of Nanoparticles

Daksh Daksh[1], Dr. Anke Kaltbeitzel[1], Mr. Gunnar Glaßer[1], Dr. Ingo Lieberwirth[1], Prof. Dr. Katharina Landfester[1]
[1]Max Planck Institute for Polymer Research, Mainz, Germany

IM-13 (1), Lecture Theater 5, august 27, 2024, 10:30 - 12:30

Background incl. aims
Various microscopic methods such as scanning tunneling microscopy, atomic force microscopy, electron microscopy, and confocal laser scanning microscopy are already present in the ongoing research scenario and provide a lot of information to researchers. Each of these microscopic methods provides different information about the local structure of the sample under investigation, depending on the interaction of the probe with the sample. In general, the information obtained from two different microscopy methods is complementary. Correlative Light- and Electron Microscopy (CLEM) is the potential tool for determining the localization and identification of biological images combining different fluorescence labelling image with an electron microscope image. Automated Multi-modal registration with reference to the prediction of landmarks is a very challenging problem. We demonstrate the image registration of correlative light and electron microscopy (CLEM) images with the precise localization of landmark positions using a training-free, unsupervised deep learning approach.
Methods
Microscopy imaging with Deep Learning (DL) have transformed the field of biological sciences and is expected to be capable of providing relevant features of images to perform complex analysis tasks. The imaging problems include image segmentation or classification [1], object detection and image resolution are experimentally performed using Deep Learning methods. Deep learning techniques such as deep neural networks (DNNs) have produced ground breaking performance for computer vision and image classification. Image registration is the very first and crucial step for intracellular studies. This is achieved by aligning two different images of the same object taken by different image sources [2]. Images with different modalities can provide additional and unique information about the localized structures [3] e.g. cells, tissues, proteins, etc. Till now, various methods are proposed and even implemented either based on neural networks or supervised approach but they all are manually driven, require lot of time and high accuracy for landmarks. So, we implement a DL based architecture to achieve the multi-modal image registration without using any landmark assumptions or modeling of the images.
Results
CLEM technique is used to get information at different length scales. The electron microscopy provides high resolution with detailed information of the sample to the nano level and the fluorescence microscopy highlights the different regions of interest using fluorescent labels. We apply feature mapping is achieved through a deep neural network and we optimized the homography hyperparameters using different learning rates at each hidden layer of neural network and regularly optimize for the minimized neural estimation loss (MINE) and generates the transformation matrix. With the calculated transformation matrices, the fluorescence channel can then be overlaid on the EM image quite easily with pixel accuracy for CLEM output. The obtained CLEM micrograph can be viewed in the graphic figure.
Conclusions

We are presenting an unsupervised DL approach for registering CLEM datasets with automated unsupervised localized landmarks. The DNN was trained by using training free MINE network with matrix exponential. It is time efficient and can handle CLEM data up to an image size of 5120 x 5120 pixels (even RGB images) and, due to the generated transformation matrices, registration of multi-channel images are also possible. The bottleneck of our neural network depends on the estimation that how fast and accurately the network optimized itself. Our DNN identifies the required features as precisely as the manual landmark based methods and promises to provide better optimized results. For training DNN, we do not require any image dataset and it is optimized in approx. 5 hours and after that, it does not require any further optimization for linear image pairs. Thus, the computing time is reduced to a few seconds per image pair and therefore, it is possible to process a large number of image datasets in a very short time even without human supervision or training.

Distortions correction in HR-(S)TEM and low resolution TEM images: absolute size, strain and polarization measurements

Dr. Nikolay Cherkashin[1], Mrs Sylvie Schamm-Chardon[1]
[1]CEMES-CNRS, Toulouse, France

Poster Group 2

Background incl. aims
TEM and STEM imaging are widely used techniques for visualizing and quantifying shape, size, density, composition, strain and structure in solid state materials at micro-, nano- and subnanometer scales. Such images are subjected to different types of distortions and calibration errors. For the purpose of fully quantitative analysis, these distortions should be removed. We propose here several methods for the correction of low magnification TEM, high-resolution TEM (HR-TEM) and STEM (HR-STEM) images, followed by their quantitative analysis.
Methods
For the correction of low magnification images taken at a basic conventional TEM we apply the technique named “Moiré by specimen design” (MoSD) [1] which allows to measure deformation and displacement in single-crystal structures, in cross-sectional and plan view geometries, with nanometric resolution over a micrometer field of view. The method is based on a specific sample preparation of a stack of two superimposed rotated lamellas of known single crystal that provides the formation of “controlled” moiré images. The deviation of experimentally obtained pattern from the anticipated one can be quantitatively mapped in form of a displacement field by reciprocal space treatment. We developed a method which allows to correct any other image for these distortions.
For HR-(S)TEM images, we present a method named “Absolute strain” (AbStrain) [2]. It allows for quantification and mapping of interplanar distances and angles, displacement fields and strain tensor components with reference to a user-defined Bravais lattice and with their corrections from the image distortions. AbStrain goes beyond the restriction of the existing method known as geometric phase analysis by enabling direct analysis of the area of interest without the need for reference lattice fringes of a similar crystal structure in the same field of view.
For the case of a crystal composed of two or more types of atoms, we also present a method named “Relative displacement” [2] for measuring relative atom displacements of the sub-structures in the unit cell, the quantity being in link to the intrinsic polarization.
Results
We applied the first method for the correction of low-magnification TEM images taken with old generation Jeol2010 TEM. The images contain layers of different thickness, nanoparticles and dislocations, which require a statistical analysis of their size, density and volume fraction. Before correction, the relative errors in the measured values are estimated of 5%, 10% and 60%, respectively. The correction allowed a drastic enhancement in the accuracy of measured values by an order of magnitude.
We demonstrated a successful application of AbStrain and Relative displacement to HR-STEM images of functional oxide and semiconductor heterostructures. BaTiO3/SrTiO3 ferroelectric heterostructure grown on silicon and InGaN 2D layers and 3D islands embedded in GaN will be of particular concern.
Conclusion
The first method proposed here enhances the precision in quantification of nanomaterials dimensions by using low magnification TEM images, that paves the way for elucidating their growth laws based on justified numbers. The 2 other methods extend the range of possible crystalline

materials that can be analyzed by the treatment of their HR-(S)TEM images. For example, nanoparticles embedded within different types of matrices, free-standing nanowires, high-angle grain boundaries, multiple stacks of heterostructures of complex oxides and semiconductors, anti-phase domains and defects inducing long range displacements, constitute just a part of the list of such materials.

Correlative TEM and APT studies of metallic Mg specimens prepared and analyzed under controlled environments

Cecile Bonifacio[1], Daniel Perea[2], Pawel Nowakowski[1], Mary Louise Ray[1], Paul Fischione[1]
[1]E.A. Fischione Instruments Inc., Export, USA, [2]Pacific Northwest National Laboratory, Richland, USA

Poster Group 2

Background
Successful correlative transmission electron microscopy (TEM) and atom probe tomography (APT) studies on metals require a surface and subsurface with minimal defects. The potential of these powerful analytical techniques can be hindered by surface damage during material processing, implanted Ga during focused ion beam (FIB) specimen preparation, or environmental degradation during specimen transfer in an ambient environment. Therefore, specimen preparation is a critical component of successful correlative analyses. We present a sample preparation and analysis workflow under controlled environments using broad Ar ion beam milling of the bulk sample and post-FIB condensed Ar ion beam milling of APT specimens. The aim is to differentiate the sub-surface properties of a metallic sample related to Ga diffusion by FIB preparation and by post-FIB condensed Ar ion beam milling using a controlled environment workflow; APT specimen yield from ambient versus controlled environment sample preparation also will be compared.

Methods
Under controlled environments, bulk Mg foil ribbons (hot rolled and deformed) were prepared using a broad Ar ion beam milling system [TrionMill, Fischione Instruments] to remove surface artifacts. The bulk sample was then transferred in a protected environment to a FIB system for imaging and electron backscattered diffraction (EBSD) analysis. Specific regions on the Ar ion beam milled sample were selected (Fig.1, areas 1 and 2); from these regions, APT specimens were prepared. Areas with multiple grain boundaries were selected to elucidate the distribution of Ga in the Mg specimen during specimen preparation [1]. FIB specimen preparation of the APT specimens followed by post-FIB condensed Ar ion beam milling [NanoMill® TEM specimen preparation system, Fischione Instruments] and subsequent TEM and APT characterization were performed in protected environments. APT characterization involved the use of an environmental transfer hub (ETH) station [2] to transfer the APT specimen to a local electrode atom probe system [LEAP®, CAMECA].

Results
Surface damage and oxides on the bulk were successfully removed by broad Ar ion beam milling based on the resulting pristine surface (Fig. 1a), which is polycrystalline with sub-micron grain sizes that average 600 nm. EBSD analysis of an area near the crack region (Fig. 1a, pink region) found smaller grains; multiple grain boundaries (marked in Fig. 1b) were identified on the band contrast image and inverse pole figure (IPF) map. The acquired TEM image (Fig. 1c) showed the presence of the FIB Pt cap layer (Fig. 1a, area 1), while the post-FIB condensed Ar ion beam milled specimen (Fig. 1a, area 2) showed the removal of the Pt layer from the TEM image (Fig. 1e). The Ga APT reconstructions displayed a significant amount of Ga at 18.7 atomic %, especially on the specimen's surface following Ga FIB milling (Fig. 1d), which is reduced to 3.9 atomic % following post-FIB Ar ion beam milling (Fig. 1f). The dark contrast on the bright field TEM image of the post-FIB condensed Ar ion beam milled specimen (Fig. 1e) correlates to the Ga-rich area marked on the Ga APT reconstructions. Using this feature, the position of the grain boundary decorated with Ga along the

vertical axis of the APT specimen was identified (Fig. 1f). For both APT specimens after Ga FIB and Ar ion beam milling, low amounts of O and H (Fig. 1g,h) within the Mg-rich region were observed. At the interface of the Mg and Ga-implanted region, parallel trends of increasing amounts of O and Ga from the Ga FIB specimen (Fig. 1g) were detected. In contrast, the post-FIB condensed Ar ion beam milled specimen showed a constant amount of O at 0.50 atomic % across the specimen. Additionally, diffusion of Ga via the grain boundaries of the polycrystalline specimen occurred during FIB preparation as evidenced by the Ga-rich line along the APT specimen (Fig. 1h, inset).

Conclusion

The broad Ar ion beam milling, Ga FIB, and condensed Ar ion beam milling workflow – all under controlled environments – removed specimen surface damage, oxidation, and Ga implantation from the specimens. Consequently, the metallic nature of the Mg sample was conserved. Ga diffused to the grain boundary of the post-FIB Ar ion beam milled specimen, which correlates to previous study [3]. The formation of Mg oxide on the FIB-prepared specimen possibly occurred due to FIB-induced thermal effects [4]. APT compositional analysis showed that surface oxidation was suppressed by controlled environment transfers.

Determination of 3D strain fields from dynamical diffraction effects

Dr. Laura Niermann[1], Mr. Tore Niermann[1], Mr. Michael Lehmann[1]
[1]Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany

IM-06 (3), Lecture Theater 1, august 30, 2024, 14:00 - 16:00

Background incl. Aims
Strain fields have a large influence on many material properties. Examples range from electronic properties like the band gap or charge carrier mobilities in semiconductors to structural properties like nucleation energies of extended defects. Several techniques for a nanometer-resolved measurement of strain fields within the S/TEM are available, like nanobeam electron diffraction, geometric phase analysis, or dark field electron holography (DFEH). However, these methods typically only reveal strain field variations in directions perpendicular to the electron beam and assume a constant strain field in the beam direction. Within these methods, dynamical diffraction effects are often seen as a nuisance since they often complicate the interpretation of the data. However, strain fields are seldom purely two-dimensional and often also exhibit inhomogeneities along the electron beam. Here we show that dynamical diffraction effects can be leveraged in several ways to obtain information about the 3D strain field.
Methods
We use the scanning convergent beam electron diffraction (SCBED) with non-overlapping disks to capture the dynamical diffraction data, where for each scan point a CBED pattern is obtained. The scan coordinates add spatial context to the individual CBED patterns, which enables their comparison with numerical strain field models.
We demonstrate the validity of this approach by investigating the dynamical diffraction effects originating from an epitaxially grown layered structure, where the layer exhibits a 45° angle with respect to the specimen surface. The inclined layer creates a well-known inhomogeneity of the strain field in the beam direction. Due to the 45° inclination of the layer, the depth of the inhomogeneity is constantly changing with the lateral position of the beam. The specimen is investigated under systematic row conditions with reflections in the direction perpendicular to the layer. The SCBED data then can be fully represented by a reduced two-dimensional (q, x)-dataset, where both the spatial dimension x and the diffraction dimension q are oriented in the direction perpendicular to the layer.
Additionally, we performed DFEH measurements of the specimen. As DFEH requires parallel illumination, a beam tilt series is acquired to achieve similar (q, x)-datasets. In contrast to the SCBED data, the DFEH datasets also contain the phase of the diffracted beam [1].
Results
The experimentally obtained (q, x)-data are compared with simulated (q, x)-data, which are calculated from a strain model using numerical multi-beam propagation of the Darwin-Howie-Whelan equations. A very good agreement between the experimental and simulated plots is found. The results show that the inclusion of surface relaxation effects into the strain model becomes mandatory for matching the simulation to the data, which further demonstrates the high sensitivity of the dynamical diffraction data to the 3D strain field.
A striking feature of these (q, x)-data is a mirror symmetry with respect to the specimen's midplane, which is also expected theoretically [2]. This mirror symmetry forbids discrimination between the case where the strain inhomogeneity is located at a certain distance behind the entrance surface of the specimen from the case where the inhomogeneity is located at the same distance before the exit

surface. However, this midplane symmetry occurs only in the intensities of the diffracted beams, not in the diffracted beam's phases. The phases recorded in the DFEH tilt series do not exhibit this ambiguity and allow even the differentiation between these cases and thus the unique determination of the depth of the inhomogeneity.

Conclusion

Within dynamical diffraction effects information about the 3D strain field is encoded. Using techniques like SCBED or DFEH tilt series allows to record dynamical diffraction data obtained from small variations of the incident beam tilt together with spatial information. This data can be quantitatively compared with numerical strain field models. The determination of the 3D strain field enables several new applications: for instance, the depth and Burgers vectors of dislocations can be obtained from a single 4D-STEM measurement [3]. Another example is the determination of the thickness and concentration of layers in semiconductor heterostructures by detailed measurements of the strain relaxation at the specimen surfaces.

Paleopalynology of Holocene birch hybridization in Iceland

Kesara Anamthawat-Jonsson[1]
[1]Institute of Life and Environmental Sciences, University of Iceland, Reykjavik, Iceland

Poster Group 1

Betula L. (birch) is a genus of about 50–60 tree species distributed throughout the temperate, boreal, and arctic regions of the Northern Hemisphere. Birch woodlands are an integral component of the tundra biome, and birch is one of the key broad-leaved tree species of the circumpolar boreal forest. Birch woodlands in Iceland, which cover around 1.5% of the total land area, are composed of 80% birch shrubs less than 2 m tall. Similar birch shrubs, often referred to as mountain birch, are found in Fennoscandia, northern Russia, European mountain regions and beyond. Previous botanical, cytogenetic and molecular genetic studies have shown that shrub-like birch in Iceland is the result of introgressive hybridization between the two co-existing Betula species, the arctic dwarf birch (Betula nana) and the European downy birch (B. pubescens). As dwarf birch is a diploid species and downy tree birch a tetraploid species, their hybrids are triploid. In the introgression process, triploid hybrids, which are partially fertile, can backcross with the parental species, producing progenies comprising introgressed diploid, triploid, and tetraploid plants. Triploid plants produce both normal triporate pollen (with three pores) and abnormal, aborted pollen, due to dysfunctional meiosis. The type of pollen abnormality that can be detected and quantified is non-triporate pollen (with four or more pores in the pollen wall). The presence of non-triporate pollen was therefore used in the study resented here as a marker to trace birch hybridization in the past. In this study fossil pollen in samples from peat sediments was examined. The peat monoliths were extracted from three geographically diverse locations in Iceland, from Grímsnes (S), Eyjafjördur (N) and Thistilsfjördur (NE Iceland), and throughout the Holocene epoch. Ages were calibrated based on known volcanic tephra layers and by radiocarbon dating. By measuring the size of individual pollen grains, we were able to differentiate pollen of the shrub-like downy birch (B. pubescens) from its closely related dwarf birch species (B. nana). The results revealed an establishment and a rapid expansion of birch woodland predominated by shrub birch B. pubescens soon after the retreat of the Icelandic Pleistocene icesheet. Non-triporate pollen grains were detected in samples from all three locations and throughout the Holocene, but with different frequencies. The results showed peaks of intense hybridization following woodland expansion in the initial period of the Holocene, from about nine thousand years ago, and again in the warming period of the mid-Holocene Thermal Maximum, the period between five and three thousand years ago. Triploid hybrids that were produced during the intense period of hybridization could potentially backcross with the dwarf birch or the downy birch, allowing gene flow by introgression between the two species, presumably making birch more adaptive to environmental changes. Thus, climate warming in the current era is expected to promote this introgressive hybridization resulting in a significant change of landscape of the birch woodland in Iceland. Birch woodlands are likely to become more widespread. Furthermore, introgressed shrub birch is likely to be more competitive over dwarf birch as average summer temperature rises.
Acknowledgements: I would like to thank Lilja Karlsdóttir and Ægir Thór Thórsson for their collaborative work combining paleopalynology with botanical, cytogenetic and molecular genetic analyses of woodland birch in Iceland.

Poster Group 2

Background
Reconfigurable micro-optics and on-chip integrated photonics often rely on micro-opto-electro-mechanical-systems to provide dynamical optical processing such as beam steering and focusing or optical coupling and phase tuning. In the process of design and fabrication of micro-electro-mechanical-systems (MEMS), and to assess their quality, a local and direct measurement of their motion on a point-by-point basis would provide unprecedented supporting information. Such a technique must be fast enough to track the MEMS dynamics with sub-micron resolution.
Methods
We introduce and discuss the implementation of dynamical imaging of MEMS by time-resolved scanning electron microscopy (TR-SEM). MEMS resonators are actuated in-operando close to their resonance frequencies, and a synchronized comb of electron pulses is used to image stroboscopically the device at a controlled time delay with respect to the beginning of its oscillation period.
Results and conclusions
We demonstrate the acquisition of stroboscopic movies by a proper sequential acquisition of secondary electron signal. Unprecedented information about local trajectory is provided, in the microsecond scale and at tens of nanometer lateral scale. In-operando nonlinearities in the response of the system, interpretable as related to system hardening are brought into evidence. We also discuss strategies to reach the ultrafast time scale.

Fine structure tuning for strongly correlated functionalities in high entropy oxides

Dr. Di Wang[1,2], Mr. Abhishek Sarkar[1,3], Mr. Gleb Iankevich[1,4], Mr. Zhibo Zhao[1], Mr. Horst Hahn[1,3,4], Mr. Robert Kruk[1], Mr. Christian Kuebel[1,2]

Poster Group 1

Background incl. aims
Strongly-correlated phenomena, such as, colossal magnetoresistance (CMR) and metal-insulator transitions (MIT), exhibited by perovskite manganites are accompanied and reinforced by coexistence of competing magneto-electronic phases [1]. Such magneto-electronic inhomogeneity is governed by the intrinsic lattice-charge-spin-orbital correlations, which are conventionally tailored via chemical substitution, charge doping or strain engineering. Alternately, the recently discovered high entropy oxides (HEOs), owing to the presence of multiple-principal cations on a given sub-lattice, exhibit indications of an inherent magneto-electronic phase separation encapsulated in single crystallographic phase. In this abstract we present the structure characterization at atomic resolution for a series of single-phase orthorhombic HE-manganites, (Gd0.25La0.25Nd0.25Sm0.25)1-xSrxMnO3 (x = 0 – 0.5), which combines high entropy (HE) concept with standard property control by Sr2+ (hole) doping, with the aim to extend the HE based approach to design strongly-correlated systems. High resolution scanning transmission electron microscopy (HR-STEM) and integrated differential phase contrast (iDPC) imaging have been used to determine the crystal structure variations in HEO introduced by different Sr concentrations. Electron energy-loss spectroscopy (EELS) has used to reveal the Mn valence change with Sr doping levels. We aim to correlate the atomically resolved geometric and electronic structures to the finely tuned electromagnetic properties of the series of Sr doped HEOs.
Methods
The powder samples were synthesized using nebulized spray pyrolysis (NSP) technique. The details of the synthesis procedure can be found elsewhere [2]. A double aberration corrected transmission electron microscope Themis Z (Thermo Fisher) equipped with a Super-X energy dispersive X-Ray detector and Gatan GIF Continuum 970 HR + K3 IS camera (operated at 300 kV) were used to examine the specimens.
Results
From the high-angle annular dark-field (HAADF) STEM images, the strong orthorhombic distortion can be identified for x = 0 (Figure 1a). The distortion becomes weak with increasing the Sr concentration. For x = 0.5 system (Figure 1b), the crystal structure is very close to pseudo-cubic. However, the higher symmetric phase shows noticeably higher density of different types of lattice defect, including twin boundaries and Ruddlesden-Popper faults, as reveled by iDPC and HAADF images in Figure 1c along [01-1] and [001] zone axis, respectively. Figure 1d and 1e present the HAADF STEM image and the corresponding atomically resolved elemental distribution maps for x = 0 and x = 0.5. A homogenous distribution of the rare-earth cation (and Sr for x = 0.5) on the A-site (RE) sub-lattice along with presence of Mn on the B-site sub-lattice, without any observable segregation

at the atomic length scales, can be confirmed. The change in the oxidation state of Mn can be evaluated from the integrated area ratio of the Mn L3 to L2 edges (L3/L2 ratio) and the energy difference (ΔE) for the O K-edge features between the Mn 3d feature (~ 530 eV) and the RE 5d/Sr 4d feature (~ 536 eV). The changes in the Mn L3/L2 ratio and ΔE as a function of Sr2+ doping (Figure 1f) unambiguously confirms that increasing amount of Sr2+ doping results in change of Mn valence state from ~3.1+ for 0%Sr to ~3.6+ for 50% Sr. The quantitative EELS analysis indicates that the separation of the antiferromagnetic ferromagnetic phases mainly depends on the ratio of the Mn3+ and Mn4+. More Mn4+ enhances the double-exchange interaction between Mn3+ – O – Mn4+, which increases the ferromagnetic component.

Conclusion

This initial study signals excellent potential to achieve complex magneto-electronic phase diagram with unique temperature dependencies that stem from competing magneto-electronic interactions. The unique subtle properties can be tuned by the merger of the high entropy-based design approach with the strongly correlated electron systems. The tunable electromagnetic properties are attributed to the structure changes by the high-resolution imaging and EELS analyses showing an increase in the amount of Mn4+ and a corresponding decrease in Jahn–Teller effect and the degree of orthorhombic distortion upon increasing amount of Sr2+ doping [3].

A crystallographic aspect of Li metal anodes: Understanding the functionality of lithium-ion all-solid-state batteries

Dr Pawel Nowakowski[1], PhD Cecile Bonifacio[1], Mrs Mary Ray[1], Mr Paul Fischione[1]
[1]Fischione Instruments, Export, USA

Poster Group 1

Background

Enabling the use of Li metal as an anode in all-solid-state batteries (ASSB) promises higher energy density and safer operation when compared to current Li-ion batteries due to the integration of nonflammable solid-state electrolyte. Increasing demand for safe electrical energy storage, especially in the transportation sector, has resulted in rapid and continuous growth of ASSB research [1].
It is undeniable that both cathode and anode microstructure have a direct impact on battery cell performance. The coulombic output, charge and discharge rates, and life cycle depend on grain size, boundary characteristics, and crystal orientation (texture). The small grain size tends to increase electrical resistivity, which degrades battery performance. High-angle grain boundaries are the most resistive due to corresponding strain fields, which are the result of high dislocation densities. Crystal orientation can promote intercalation, prohibit intercalation, or increase instability [2]. For example, closely packed crystallographic planes (grain facets) are favorable for higher ion mobility. Considering the many microstructural parameters and relationships between them, it is critical to evaluate the best candidate for Li metal anode before battery fabrication.
However, there is little work reported on the microstructural characterization, which allows for the evaluation and comparison of various lithium metal sources.
Li is highly sensitive to oxygen, nitrogen, water, and carbon dioxide, which makes sample preparation for microstructural characterization impossible in ambient atmosphere. Lithium is also a very soft material, and its crystallographic structure can be easily damaged by mechanical interaction. The inherent characteristics of lithium metal demand a controlled environment workflow from sample preparation to structural investigation in a scanning electron microscope (SEM). In the past few years, considerable effort has been devoted to developing accurate sample transfer technology [3].
We demonstrate a workflow that allows the evaluation and comparison of different lithium anode sources. The workflow consists of cryogenic broad Ar ion beam milling sample preparation, cryogenic sample transfer to the SEM, and microstructural characterizations. We will discuss the challenges of cryogenic observations in the SEM. All results are supported by energy dispersive X-ray spectroscopy (EDS) and backscatter electron diffraction (EBSD) measurements.

Methods

All samples [pure Li metal ribbons, Sigma-Aldrich] were prepared using a broad Ar ion beam milling system [TrionMill, Fischione Instruments]. The samples were transferred from the ion mill to a Ga FIB system [Scios DualBeam, Thermo Fisher Scientific] using cryo transfer [Actively Cooled Transfer device, Quorum Technologies Ltd. / Fischione Instruments]. The Scios DualBeam is equipped with a PP3004 airlock and PP3005 SEM/FIB cryo stage [Quorum Technologies Ltd.] All SEM analytical measurements were done using an X-Max 150 mm2 EDS detector coupled with Aztec software [Oxford Instruments] and e-FlashFS EBSD detector combined with Esprit software [Bruker Nano Analytics].

Results and conclusions

Three lithium sheets (Li-1, Li-2, and Li-3) were compared. Figure 1 shows the inverse pole figure (IPF) color-coded EBSD maps for the three samples. The average grain size is 100 µm, 150 µm, and 1150 µm (Li-1, Li-2, and Li-3, respectively). Figure 2 represents corresponding pole figures. Note that multiple maps acquired from different sample regions were used for average grain size and texture determination for each sample. Sample L1-1 is characterized by {110}<001> texture, sample L1-2 has strong rotated cube texture {100}<011> in the rolling (RD), transverse (TD), and normal (ND) reference directions, while sample Li-3 represents random texture. If one of these materials was integrated as an anode material to ASSB, the normal direction would be aligned with the Li+ mobility direction between the anode and cathode.
The {110} crystal facets have the lowest surface energy and the closely packed atom arrangement for body-centered cubic lithium structure; these characteristics contribute to high Li diffusivity, which improves cycling stability and battery lifetime [4]. Large grains are more desirable for high coulombic output, while small grains are not [5]. Therefore, larger grain sizes combined with a {110}<001> texture would be the best choice for a Li metal anode because it is likely to provide the best battery performance.
Accurately evaluating lithium anode microstructure is critically important to developing superior battery performance.

Dose fractionation and alternative scanning strategies for beam damage mitigation in event-driven 4D-STEM

Arno Annys[1,2], Dr. Hoelen Robert[1,2], Mr. Matthias Quintelier[1,2], Prof. Joke Hadermann[1,2], Prof. Jo Verbeeck[1,2]
[1]EMAT, University of Antwerp, Antwerp, Belgium, [2]NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium

Poster Group 1

The introduction of event-driven direct electron detectors, e.g. those based on the Timepix3 chip (Amsterdam Scientific Instruments CheeTah T3, Advacam AdvaPIX TPX3), has removed a major constraint in scanning transmission electron microscopy (STEM), making it possible to achieve momentum-resolution by recording the far-field intensity at each scan position with no dwell time or dose penalty. In contrast, most of the popular frame-based detectors still impose a minimum acquisition time of a few tens of microseconds. Such recording times are at least an order of magnitude larger than what can typically be achieved by the microscope's scanning system. Additionally, frame-based representations are inefficient regarding data size and processing speed, especially when using large or repeated scans. Consequently, event-driven detection has significant advantages for fast 4D-STEM data acquisition, including electron ptychography.

The development of user-programmable scan engines allows another layer of optimization, particularly with the introduction of alternative scan patterns, which have been shown to permit mitigation of the overall specimen deterioration during an experiment. This mitigation can be related to the accumulation of damage sites (e.g. charge carriers induced by radiolysis or atomic defects created by knock-on displacement) when the electron incidence is strongly localized, and the naturally occurring diffusion of those defects. The more the total electron dose is homogenized in time and space, the better the damage distribution spreads out, and the less likely local accumulations of damage sites become, thus preventing irremediable destruction of the specimen structure. When combining an optimized scan strategy with an event-driven detector, one can obtain the information richness of 4D-STEM, combined with favorable beam damage behavior, as often praised in conventional TEM.

Here, an experimental set-up that routinely allows fast dose-fractioned event-driven 4D-STEM with custom scan strategies is described. A software toolkit controls and synchronizes the scan engine and detector, performing in-line processing of the event data stream for live visualization. Initial experimental results will be presented, demonstrating the interest of dose fractionation in microprobe investigations of beam-sensitive metal-organic frameworks and high-resolution imaging. Additionally, a more fundamental and theoretical analysis of electron-induced damage diffusion statistics is performed by using a simple split operator approach, thus modeling the damage distribution function in space and time, within a given STEM recording. The cases where a fractionation of the scan window is performed or when an overfocused or time-dependent probe is employed are investigated, and conclusions are drawn regarding their potential to lower beam damage while keeping the dose constant.

Poster Group 2

Background
The shell of the bivalve Pecten maximus, also called the king scallop, was previously found to be detrimentally affected by the presence of metal contamination, in particular Cu, Pb, and Zn originating from mining activities on the Isle of Man [1]. In addition to a reduction of shell thickness, scallop shells from the contaminated area exhibit a sharp break line in the mineralization within the foliated region of both the top and bottom valves. Our data suggest that these mineralization break line caused reduced fracture strength compared to pollution-free scallops, which results in increased mortality due to predation and during the process of dredging. These break lines have already been referred to as being of aragonitic prismatic structure [2].
To shed light on the possible impact of metal contaminations on the growth and strength of scallop shells and in particular on the 3D morphology and microstructure of the scallop, from contaminated and uncontaminated sites, we used characterization tools at different length scales (from cm to µm) using electron and X-ray probes to determine areas of interest in contaminated and healthy (uncontaminated) shells to finally realize crystallographic orientation map using EBSD technique and localized 3D reconstruction by focused ion beam techniques (FIB). The aim of this study was to combine these techniques to produce a full 3D EBSD map of the crystallographic orientations of the critical zones.

Methods
The scallop samples were cut using a diamond cut-off wheel (South Bay Technology Low Speed Diamond Wheel Saw MODEL 650) to extract a large cross-section of contaminated and healthy scallop to study the whole shell section. The cross-sectioned samples were then polished with lapping pads to a felt disk with a 50 nm colloidal silica suspension, to obtain a perfectly flat surface for future SEM observations and EBSD analysis.
We first applied 3D X-ray microscopy using micro-computed tomography (microCT) scanning with a ZEISS Xradia 520 Versa X-Ray microscope, at different resolutions to locate potential structural defects or the mineralization break line on contaminated shell and healthy shell.
The same samples were then analyzed by scanning electron microscopy (SEM) coupled with elemental analysis by energy dispersive X-ray spectroscopy (EDS) to detect differences of microstructure or orientation on the shell cross section. The equipment used for this purpose is a Hitachi field emission gun (FEG)-SEM SU8230 with low voltage analysis (3KeV) by secondary and backscattered electrons (PD-BSE) imaging, Bruker XFlash EDS detector for elemental quantification point analysis, and Bruker Flat Quad detector for EDS mapping analysis. A 10 nm layer of carbon coating was necessary to be able to run long EDS mapping acquisition.

Electron Backscattered Diffraction analyses were conducted for both types of samples on a SU3500 SEM from Hitachi under VP-SEM mode at 20keV on main areas detected by the previous SEM analyses.
The FIB tomography is performed using a Hitachi Ethos NX5000 FIB-SEM to obtain a stack of images and the Dragonfly software from Comet [3] to build the 3D volume samples from each type. In addition, the FIB-SEM NX5000 is equipped with a Symmetry S2 EBSD camera from Oxford Instruments that can allow us to obtain stacks of EBSD maps to build 3D volumes with crystallographic orientation information.

Results
MicroCT analyses carried out at different resolutions (from 30 µm to 2.5 nm pixel size) have shown that the break line visible in the contaminated shell is also present in healthy shells, but less marked and finer than that observed in the contaminated shell. These lines extend across the entire shell surface, although their point of initiation remains a mystery.
SEM analysis enabled us to observe the variation in microstructure across the entire cross-sectional area and to determine the zones of interest for the different microstructures observed in each type of shell. The zone we call the "break line" presents a prismatic microstructure as expected, different from the microstructure observed in the main parts of the shell, largely composed of elongated and foliated grains. In addition, a detailed analysis of the samples revealed the presence of a main prismatic layer, which was found to be thicker in the contaminated samples, and we were also able to observe several thinner prismatic layer in both types of sample.
EBSD analyses, carried out on various zones of interest selected from SEM observation, confirmed that the foliated microstructure is calcite. We detected that the prismatic layer was indeed clearly well-crystallized aragonite for the disruptive line. EBSD maps obtained in regions containing thinner disruptive layers reveal that there is no detection of specific crystallographic orientation.

Conclusion
The combination of microscopy techniques using electron probes and X-rays at different length scales has enabled us to gain a better understanding of the structure of scallop shells and the impact of metal contamination from mining on the Isle of Man.
After a detailed study using microCT and low voltage SEM, targeted EBSD analyses revealed that the break lines present over the entire shell surface in all shells are prismatic in structure and are associated with the aragonitic myostracial layer, while the rest of the shell is predominantly composed of calcite with a foliated microstructure. This aragonitic layer, well crystallized in its thickest zone according to EBSD results, shows no detectable crystallization in its thinnest zone. A more in-depth study of these areas would help determine the cause of this lack of identification.
EBSD mapping acquired with the FIB-SEM NX5000 will enable us to obtain 3D volumes with crystallographic orientation information for healthy and contaminated shells, allowing us to compare growth and development of each type of scallop and detect defects in shell crystallization depending on their environment.

Poster Group 2

Background incl. aims
The shift towards environmentally friendly fuels has led to stricter regulations on transportation fuel purity, necessitating more efficient catalysts for high-quality, low-sulfur diesel from both fossil and renewable sources. Co-Mo catalysts, supported on alumina, are used to remove sulfur from organosulfur molecules in mineral oil in industrial processes conducted under high hydrogen pressure. However, a significant challenge remains in extracting sulfur atoms from certain sulfur compounds, such as 4,6-dimethyldibenzothiophene (4,6-DMDBT), due to steric hindrance in the molecular reaction pathway.
Over the last four decades, our understanding of Co-Mo catalysts has greatly improved, largely thanks to the Co-Mo-S model introduced by Dr. Henrik Topsøe and his team [1]. According to this model, the active phase of the catalyst is MoS_2 nanocrystals with Co atoms attached at the edges [1,2]. Similar detailed atomic-level imaging of industrial catalysts has remained a challenge since the catalysts are prepared by incipient wetness methods on high-surface area (oxide) supports. However, recent advancements in aberration-corrected electron microscopy, which now allow for single atom detection, have extended this understanding to industrial-grade catalysts supported on high-surface area (conducting) materials, such as graphite, by imaging atom-by-atom the Co-Mo-S structure, even in 3D [3,4]. This has been available due to a combination of ultra-thin supports for single atom contrast optimization and low-voltage (60kV) and low-dose imaging schemes to suppress beam damage.
These breakthroughs provide a powerful set of tools for designing and characterize new active edge and corner structures in hydrotreating catalysts. Here, we present such an approach to enhance a commercial alumina-supported Co-Mo catalyst with small amounts of Pt [5]. This has significantly increased the catalyst's hydrodesulfurization (HDS) activity, boosting the process of removing sulfur from diesel distillates, including 4,6-DMDBT molecules, by +46% in a pilot test unit under industrial conditions. The tested catalysts are analyzed using atomically resolved scanning transmission electron microscopy (STEM) to precisely pinpoint the location of the Pt promoter atoms. These findings are compared to DFT studies based on the well-established Co-Mo-S model. Furthermore, the desulfurization process of 4,6-DMDBT molecules will be modeled to shed light on the catalytic role of Pt.

Methods
The Pt-Co-Mo catalysts were synthesized by incipient wetness impregnation on a mesoporous shaped alumina carrier, resulting in catalysts with metal loads of 16 wt% Mo, 3.5 wt% Co, and between 0 and 1.9 wt% Pt [5]. The catalysts were tested for their HDS activity in a pilot unit using a diesel oil feed containing 1.22 wt% sulfur. After the HDS process, the catalysts were cleaned with the solvent dichloromethane to remove any remaining oil residues. The catalysts were then characterized by scanning transmission electron microscopy (STEM) using two different microscopes;

a FEI Talos F200X for element mapping (EDX), and a probe-corrected JEOL ARM-200F for high resolution imaging, operated at 200kV with a probe size of ~1Å for single-atom detection. The interpretation of these results was aided by STEM image simulations conducted in QSTEM, and density functional theory (DFT) calculations of Pt and Co-Mo-S interactions to visualize edge motifs of the Pt-Co-Mo-S catalyst. The nature of Pt was further justified by Pt L-edge X-ray absorption near edge structure (XANES).

Results
Here we present the synthesis of platinum-cobalt-molybdenum (Pt-Co-Mo) catalysts and their application in the hydrodesulfurization (HDS) process. The resulting catalysts showed a significant increase of +46% in HDS activity when tested in a pilot unit under industrial conditions. Surface science studies using scanning tunneling microscopy (STM) and density functional theory (DFT) have provided a detailed understanding of the catalysts' edge-motifs in Co-Mo-S structures at the atomic level [2]. These model studies, prepared on planar Au substrates under ultra-high vacuum levels, suggest that the cobalt atoms act to increase the concentration of sulfur vacancies on the MoS_2 edges and that corner sites provide favorable geometries for adsorption of specifically the sterically hindered 4,6-DMDBT molecules. Therefore, we focus on characterizing the Pt-Co-Mo catalysts at the atomic level using Pt L-edge XANES and high-resolution STEM. The results revealed a tertiary transition metal sulfide nanostructure, Pt-Co-Mo-S, with Pt attached to edges and corner sites of the Co-Mo-S structure. The study also utilize DFT calculations to further understand the catalytic working principle and the promotional role of Pt in ultra-deep hydrodesulfurization, especially the desulfurization of refractory 4,6-DMDBT molecules.

Conclusion
This study reveals that a Pt-Co-Mo-S nanostructure, with Pt strategically positioned at the edges and corners of the Co-Mo-S structure, significantly enhances the desulfurization process, particularly for bulky 4,6-DMDBT molecules. The introduction of Pt in these tertiary structures appears to break the conventional scaling relations, modifying the behavior of corner and edge sites in the Co-Mo-S catalyst. These single-atom level insights into complex edge motifs in industrial catalysts elucidate the role of promoter elements and provide a new perspective on how to tailor nanostructures for more efficient catalysts in the future.

Strain mapping using high-resolution electron backscatter diffraction technique: The influence of sample preparation

Dr Pawel Nowakowski[1], Mrs Mary Ray[1], Mr Paul Fischione[1]
[1]Fischione Instruments, Export, USA

Poster Group 2

Background

When developing a new metallic alloy, one of the critical parameters is how it will resist expected loads without failure. Understanding how materials deform is important when doing research and development in fields such as aerospace, where public safety is the top priority. An emerging strain distribution measurement technique is based on cross-correlation analysis of high-resolution electron backscatter diffraction (HR-EBSD) patterns. The technique measures lattice distortion-related differences between EBSD patterns obtained within the same grain. The HR-EBSD technique was applied to elastic strain, evidence of plastic strain, and geometrically necessary dislocations (GND) measurements [1]. However, aside from intrinsic instrumentation limitations, HR-EBSD is very sensitive to diffraction pattern quality. Therefore, sample preparation factors prominently into the accuracy and precision attained in HR-EBSD strain analyses.
However, it is not easy to distinguish between the residual real strain present in a material and the strain induced by sample preparation. To be able to persistently illustrate the effect of stress on the microstructure during sample preparation, we have chosen the phenomenon of dynamic strain-induced transformation (DSIT) of austenite to surface martensite [2, 3]. The DSIT can occur during sample preparation by mechanical polishing (MP) or while using ion beam-based sample preparation techniques: focused ion beam (FIB) or broad ion beam (BIB) [4, 5]. We prepared a series of austenitic precipitation hardening grade steel samples using MP, BIB, and FIB techniques and exposed an austenitic precipitation hardening grade steel to Ga ions at a variety of beam energies and sample geometries. Energy-dispersive X-ray spectroscopy (EDS), electron backscatter diffraction (EBSD) and high resolution (HR)-EBSD techniques were used to assess structural damage induced by sample preparation.

Methods

The samples were mechanically polished by colloidal silica on a grinder/polisher tool [MultiPrep™ system, Allied High Tech Products]. Then the samples were prepared by broad ion beam milling [TrionMill, Fischione Instruments]. Finally, the samples were exposed to Ga ions at a variety of beam energies and milling geometries in a FIB system [Scios DualBeam Ga FIB system, Thermo Fisher Scientific].
After each sample preparation technique, the samples were analyzed using:
- a Ga FIB system equipped with an EDS detector [X-Max 150 mm2 EDS detector with Aztec software, Oxford Instruments] and an EBSD detector [e-FlashFS EBSD detector with Esprt software, Bruker Nano Analytics], and
- a scanning transmission microscope [S-4700 SEM, Hitachi] equipped with an EBSD detector [NordlysNano EBSD detector with Aztec software, Oxford Instruments].

EBSD data were processed using HKL Channel 5 software [Oxford instruments]. High HR-EBSD measurements were done using Open X-Y software [Brigham Young University].

Results and conclusions

Figure 1 shows HR-EBSD average strain measurements and geometrically necessary dislocations (GND) of steel samples after mechanical polishing (Fig. 1a, 1c) and BIB milling at 5 keV, 2 keV, 1 keV, and 3° milling angle (Fig. 1b, 1d). No DIST phase transformation of austenite to martensite is observed in the sample prepared by BIB milling. In the sample prepared by MP, 20 % strain-induced martensite is observed. Figure 1a shows an HR-EBSD average strain map of partially transformed martensite to austenite grains. Strain accumulation of up to 10-2 of austenite grains around martensite can be observed. This strain gradient can be correlated with the high GND densities shown in Fig. 1c. Compared to the sample prepared by a BIB mill, the GND density is higher – up to two orders of magnitude. No strain is observed in the BIB milled sample. The BIB milled sample with no presence of DIST of austenite to martensite was exposed to Ga FIB at different ion beam energies. The area affected by the Ga ion beam had a very poor quality EBSD pattern (Kikuchi bands shift and overlap). The EDS analyses demonstrate strong Ga ion implantation. Figure 2a shows the HR-EBSD average strain map of regions both exposed and not exposed to a 1 keV Ga FIB. In contrast to the MP sample, no strain gradient correlated with GND density is found. Figure 2b shows {100} crystal plane orientation facing the Ga ions bombardment. The part of the grain exposed to the Ga FIB shows high strain accumulation. This suggests that structural damage is dependent on grain crystallographic orientation. Structural damage and strain accumulation result from FIB-induced atom displacement and vacancies, which leads to strain-induced austenite deformation to martensite.

Background incl. aims
Conducting both electrochemical and structural/compositional analysis simultaneously and on a nanoscale level enables a direct correlation between electrochemical performance and the material's properties, tracking their changes over time and different operational conditions1. The aim of the presented work is to establish a solid method that combines high-temperature solid state electrochemical analysis with (S)TEM2,3. Such a method is crucial for advancing solid oxide electrolysis and fuel cells (SOEC/SOFC) and can be relevant to other solid-state electrochemical technologies such as solid-state batteries and thermoelectric devices.

Methods
A method development is presented in which MEMS chip-based heating-biasing TEM holders are combined with environmental TEM (ETEM) and a potentiostat for electrochemical impedance spectroscopy (EIS). Various preparation methods and TEM sample geometries are included, such as model solid oxide cells prepared by pulsed laser deposition (PLD), along with an advanced FIB-SEM sample preparation procedure. Operando high-temperature electrochemical (S)TEM experiments are conducted.

Results
The feasibility of conducting electrochemical cell tests in the (S)TEM is demonstrated, including reliable EIS measurements of full solid oxide cells at temperatures up to 800 ˚C in gases such as O2 and H2/H2O and with applied electrical polarization1,2. The presentation will discuss challenges and necessary requirements for performing such experiments2. Examples of EIS analysis in the TEM will be presented1,2. Additionally, results from experiments are presented where polarization-induced degradation at an electrode-electrolyte interface in an SOEC was indicated by EIS analysis and confirmed by electrochemical operando STEM observation.

In situ observation of dislocation evolution in cerium oxides nanocubes in an environmental TEM

Dr Lucile Joly-Pottuz[1], Dr Rongrong Zhang[1], Dr Thierry Epicier[2], Dr Gaetan Laurens[3], Dr Tristan Albaret[3], Pr Karine Masenelli-Varlot[1]
[1]MATEIS - INSA, , France, [2]IRCELYON - UCBL, , France, [3]ILM - UCBL, , France

Poster Group 1

Characterizing the mechanical properties and deformation mechanism of ceramic materials at the nanoscale is of much interest to improve their processing and properties. At the nanoscale, plastic deformation have already been observed in alumina and magnesium oxide nanoparticles at room temperature. Cerium oxide, as one of the most important ceramic materials, is widely used in many applications, such as in solid oxide fuel cell electrodes, catalysis, or gas detection. However, there are few experimental pieces of evidence of the evolution of defects, which have significant impact on many material properties, especially on mechanical behavior. TEM observations of CeO2 nanocubes demonstrated a beam sensitivity with reduction under high electron dose. Reduction may have an impact on the mechanical properties. The development of TEM nanocompression experiments inside an environmental transmission electron microscope (ETEM) is of much interest to study the mechanical properties of ceramic particles and the effect of the reduction on them. High resolution imaging may also be very useful to fully study the defects formation (dislocations, stacking faults…) during compression. In situ nanocompression under gas and at high resolution in an ETEM were developed on CeO2 and are reported in this work.

Cerium oxides nanocubes (20-50nm size) were compressed using a dedicated Hysitron PI 95 sample holder in an environmental transmission electron microscope (ETEM). By controlling the electron dose and by using a small pressure of air in the ETEM, different CeOx structures (x between 1.5 and 2) were tested to compare their mechanical properties and their deformation mechanisms. Displacement-controlled in situ compression tests were performed in a Titan ETEM 80-300 kV microscope equipped with a Bruker PI95 picoindenter. The loading direction was [100]. Different imaging techniques have been used to identify the slip systems in CeO2. High resolution imaging has also been performed during compression of Ce2O3 nanocubes to observe dislocations, stacking fault or nano-twin formation. Simulation calculations (DFT, DM) are very useful to complete/understand the in situ nanocompression experiments and were developed on CeOx material, even if computing time might be long due to the complexity of the structures

.

CeO2 has a fluorite structure (space group Fm-3m). Their reduction under the electron beam creates oxygen vacancies in the structure, which leads to a fcc bixbyite structure (space group Ia-3) with a double cell parameter compared to fluorite. In the case of CeO2, deformation mechanism is found to be similar to those observed in other fluorite structure, with <110> {111} slip systems. The evolution of the yield stress with the nanocube size reveals to be similar to the one already observed for other fcc structures. In the case of Ce2O3 bixbyite structure few studies have reported the deformation mechanism and the slip systems so far. Oxygen vacancies may play a role in defect formation. To observe the deformation mechanisms accurately, high resolution imaging could be performed during in situ nanocompression. Dissociation of perfect dislocations into partials and stacking faults has been observed, which is unusual in oxides. The results obtained for both structures are discussed and compared to simulations works. Compression cycles carried out on the

same nanocube under different irradiation conditions (thus either in the fluorite or in the bixbyite structure) will be shown to highlight the differences between both mechanisms.
.

In situ nanocompression experiments have been used to study and compare the deformation mechanism of CeOx nanocubes. On single nanocubes, different mechanisms have been evidenced depending on the irradiation conditions and thus the crystallographic phase. When compressed along the <100> direction, fluorite deforms at room temperature via <110> {111} perfect dislocations and the effect of the nanocube size on the yield stress is similar to what is observed in other fcc materials. In bixbyite, the dislocations dissociate and form stacking faults. This process is reversible.

Deformation mechanisms of inorganic fullerenes used as lubrication additives: an in situ TEM nanocompression study

Dr Sankar RK Pattamadai Sundaram[1], Dr Lucile Joly-Pottuz[1], Dr Pavel Afanasiev[2], Miss Marina Benmansour[3], Pr Fabrice Dassenoy[3], Pr Karine Masenelli-Varlot[1]
[1]MATEIS - INSA Lyon, Villeurbanne, France, [2]IRCELYON - UCBL, Villeurbanne, France, [3]LTDS - ECL, Ecully, France

PS-12, Lecture Theater 2, august 29, 2024, 10:30 - 12:30

Energy saving is a crucial point to hinder environmental issues. Lubrication of systems, especially engines, have been improved but further developments are still mandatory. Energy loss and wear of moving parts have to be decreased. Inorganic fullerene-like – IF- nanoparticles made up of metal disulphides MoS2, WS2 are considered as promising candidates for anti-wear and anti-friction additives. It was first thought that their round shape will allow them to act as small ball bearings inside the contact but an exfoliation mechanism has been observed [1,2]. This exfoliation leads to the formation of lubricant sheets in the contact area. TEM nanocompression experiments allowed to observe this exfoliation in situ [3]. Depending on the synthesis conditions, fullerenes can present a well-defined onion-like structure with a hollow center or can be composed of not well aligned MoS2 sheets without hollow center. This difference of structure leads to different tribological results. To better understand this discrepancy of behavior, in situ TEM nanocompression/nanofriction experiments were performed on both types of structures to mimic what can happen in the tribological contact. Furthermore, the chemistry of the IF nanoparticles may have an impact. In situ testing experiments were performed under vacuum and under oxygen to monitor the effect of oxygen on their behaviour inside the tribological contact.

MoS2 nanoparticles with controlled sizes and structures were prepared by exposing sheelites MoMO4¬ nano particles to a H2S-CCl4-Ar gas mixture [4]. After dispersion in a solvent by sonication, they were deposited on a silicon substrate mounted on a copper pallet attached to the Bruker/ Hysitron PI-95 TEM holder. In situ compression and friction behaviour of MoS2 nanoparticles with different level of crystallinity (poor, medium, high) under vacuum and oxygen atmosphere were performed, in an aberration corrected environmental TEM microscope (FEI Titan ETEM). Poorly crystalline fullerenes present a structure with a random orientation of MoS2 sheets. Medium and highly crystalline fullerenes present an onion-like structure, highly crystallinity having less defects. The structural changes of nanoparticles under compression and/or during friction were imaged in TEM bright field mode with a 25 frames/s acquisition rate. A precise processing, by following the change of the particle shape and the presence of shear, was determined to fully characterize and understand the deformation mechanism. Observations were linked to the force-displacement curve.

Comparison of compression experiments for the different crystallinities present different deformation mechansims. For the low crystallinity sample, orientation of the sheets perpendicular to the compression axis is observed during compression and shearing (see figure). For onion-like medium crystalline particles, buckling of the inner shell initiates the deformation, while it is not observed in highly crystalline ones. The buckling may be due to the presence of defects. The onion-like morphology leads to a large amount of elasticity and their plastic deformation to orientation of planes perpendicular to load direction. The amount of elasticity, the mechanism of deformation

initiation and the forces differ according to morphology, while at the end MoS2 sheets align to the perpendicular direction of applied load.

In situ nanocompression experiments in ETEM are useful to observe the exfoliation mechanisms of fullerenes. It was already known that the lubrication mechanism of fullerenes is based on their exfoliation. The interest here is to be able to observe the exfoliation mechanism and to compare the behavior of fullerenes with different crystallinity. A different behavior has been observed depending on their crystallinity, with both mechanisms leading to the formation of MoS2 sheets in the lubricated contact.

Background incl. aims
Over the years, the Cryo-EM community has anticipated the achievement of software automation that would simplify the Single Particle Analysis (SPA) data acquisition workflow without requiring any user setup. This advancement would enable researchers, regardless of their expertise in applications or microscopy, to effectively utilize high throughput cryo-electron microscopes, particularly in industrial settings or entry-level laboratories where efficiency and user-friendliness are crucial barriers to adoption. Notably, one of the primary challenges in SPA is the automation of screening. Thermo ScientificTM Smart EPU Software currently offers a workflow that enables automated screening of multiple samples. Here, we are expanding the capability of Smart EPU to make SPA screening a fully unattended and robust process.

Methods
By utilizing EPU, EPU Multigrid, EPU Quality Monitor (EQM), Embedded CryoSPARC Live, a novel set of AI/DL algorithms, and CryoFlow we can now demonstrate a workflow that allows users to screen an entire cassette of samples on an autoloader system without any manual interventions.
To achieve such a prominent level of automation, various aspects of the workflow have been optimized. User workflows for screening often involve acquiring and analyzing small datasets from multiple grids under different conditions to identify optimal ice thickness and particle behavior. These tasks are laborious, as users must load each grid, select grid squares with varying ice thickness, identify foil holes, select foil holes with varying ice thickness, curate initial selections, and perform data analysis on acquired high-resolution images to determine favorable conditions for further collection of large datasets. Smart EPU presents a set of innovative AI/DL plugins that automate those steps that hitherto needed manual actions. To increase robustness, we also introduced two new set of features: one to access foil hole selection by ice thickness deterministically, using plasmon imaging, which is particularly useful when working with gold grids; secondly, when the image analysis of a screening session reveals a particle preferential orientation issue, Smart EPU fully supports the session setup for automated acquisition on tilted specimens.

Results
Experimental results indicate that the autonomous algorithms perform comparably to an experienced user with a significant gain of time. Furthermore, we combine these innovations with a redesigned user interface that allows users to initiate the setup process with just one click. This screening solution is connected to EQM and Embedded CryoSPARC Live, enabling real-time acquisition adjustments and image analysis.

Conclusion
With these advancements, users will be able to load their samples, quickly initiate the screening process on site, and visualize remotely the results on the web portal of our data integration platform,

CryoFlow, while still acquiring or after completion of the screening session. This new strategy allows users an easier and efficient process for a more comprehensive understanding of their samples and better decision making about further data collection.

Scanning transmission electron microscopy of quantum centers in diamond

Diana Propst[1], Dr. Harriet Åhlgren[2,1], Prof. Jani Kotakoski[1]
[1]University of Vienna, Faculty of Physics, , Austria, [2]University of Helsinki, Department of Physics, Helsinki, Finland

Poster Group 1

Background incl. aims
Quantum centers in diamond have been a topic of extensive research for over two decades. Various dopants found naturally in diamond or introduced into the lattice artificially have been studied computationally and experimentally, investigating their properties and potential use as quantum technological devices such as qubits or quantum sensors. The most prominent example is the nitrogen vacancy center, known for its extraordinary photoluminescence qualities. Similar photoluminescent properties have been found for the silicon vacancy, germanium vacancy and erbium vacancy center, among many others. However, the atomic structure of such quantum centers hasn't been fully uncovered via scanning transmission electron microscopy (STEM) imaging so far, as these centers have been rarely imaged. Due to this, it would be important to know how these centers could look like when imaged in STEM.
Methods
In this work, STEM annular dark field image simulations of various quantum centers (N, Si, P, Ge, Er, Ni, etc.) in diamond will be discussed first, including the predicted visibility of the dopants in the diamond lattice in dependence to factors such as sample thickness, defocus, and dopant placement. The results indicate that quantum centers with dopants of atomic number higher than 50 are viable to study with annular dark field STEM imaging. Based on this, diamond samples doped with Er were prepared and imaged with annular dark field STEM for the first time, also investigating the effects of two different doping methods, with dopants induced in growth via chemical vapor deposition vs. dopants induced via ion irradiation, and varying electron beam acceleration voltage.
Results
The experimental data was found to be in agreement with the simulation results. Interestingly, it was observed that the dopants do not remain static in their positions, instead moving between images, similar to the results of a previous study on STEM of Bi in silicon samples. Stacks of consequent images of up to hundred were acquired, where the motion of the dopants can be followed. Automatic dopant tracking thus becomes a good choice for the analysis of such data, which is used to uncover the relations between the dopant movement, imaging and sample conditions.
Conclusion
This study offers new insights into the imaging of quantum centers in diamond, demonstrating that resolving their atomic structure requires special care due to their dynamic behavior in the imaging process.

IM-10 (2), Lecture Theater 3, august 29, 2024, 14:00 - 16:00

Background
As a powerful instrumentation tool, scanning electron microscopy (SEM) has been increasingly used to perform analysis on a wide range of minerals, metals, biological specimens, nanostructured materials, polymers, composites, and electronic components [1]. By integrating hyperspectral imaging techniques into SEM, secondary electron hyperspectral imaging (SEHI) technology is able to offer detailed and comprehensive spatial-spectral information of the materials, making it versatile for analysing chemical properties and surface morphology at micro- to nano-scale [2].
However, effectively visualizing spatial-spectral information can still be challenging, especially when changes in spectra are subtle due to spectral mixing or occur only in a very small percentage of the area analysed. To address this problem, we propose a novel analytical workflow for SEHI data using unsupervised learning, which can automatically identify chemical bonds or elements present in the imaged materials and additionally segment the materials surfaces into corresponding chemical groups.
Methods
The proposed automated analytical workflow includes the following steps:
(1) Microscopy image data is processed by traversing the whole field of view of the image, through small block-based or pixel-wise methods. For block-based processing, the entire image is divided into smaller, predetermined units (e.g., blocks of 3*3 pixels).
(2) For each small block, the peaks in the corresponding spectral curve, also known as spectral peaks, are identified and gathered. This allows for the collection of the overall distribution of all spectral peaks across the image.
(3) The distribution of spectral peaks is learned by using unsupervised clustering approaches. In this work, the Gaussian mixture model (GMM) approach is adopted to perform probabilistic clustering. The centroid of each GMM component reflects the location of the corresponding spectral peak, which can be used to deduce the associated chemical bonds or elements in the material sample.
(4) Image blocks that fall into the same cluster are then identified. Accordingly, the spectra of these image blocks from the same cluster are extracted. These extracted spectral signatures then act as reference spectra, or like "endmembers" in spectral unmixing processes.
(5) By evaluating spectral similarity using spectral angle mapper (SAM), the image regions, sharing similar spectral properties with these reference spectra obtained in (4), are distinguished.
Results
We implemented this framework into analysing a complex metal alloy (palladium & silver, PdAg) and carbon film, imaged using a Helios Nanolab G3 UC microscope [3]. Firstly, the raw hyperspectral image slices are registered through a template-matching algorithm [4]. By dividing the entire image into smaller blocks and identifying the localized spectral peaks from these blocks, we obtain the distribution of spectral peaks. To figure out the predominant spectral peaks within this distribution,

unsupervised clustering by the GMM is applied. As shown in Fig.1, the GMM outcomes reveal 5 components with peak locations at 0.83, 1.98, 3.57, 4.75, and 5.60 eV, respectively. According to the literature, the spectral peaks at 0.83 and 1.98 eV are likely attributed to metals Pd and Ag [3]. The peaks observed in 3-6 eV range are thought to be linked to the contributions from sp^2-like, a-CH and sp^3-like carbon bond types. Intuitively, image blocks that fall into the same cluster, primarily contribute to a particular spectral peak. Thus, the reference spectra, or endmembers-like spectra, can be extracted from the image blocks belonging to the same cluster. The SAM is utilized to assess spectral similarity against these reference spectra for image segmentation.

Conclusion

Conventional and manual microscopy data analysis methods, due to their limitations in processing efficiency and accuracy, could hinder the applications of SEHI in advanced characterization of materials. Machine learning-based approaches, especially unsupervised learning, offer promising automated analytical solutions for tackling these challenges effectively. The automated analytical workflow proposed here well identifies the chemical bonds and elements present in the imaged materials. The unsupervised clustering method, GMM, perform well in modelling the overall distribution of all spectral peaks and uncovering the chemical bonding types. According to the clustering outcomes, the materials surfaces can then be segmented into the corresponding chemical groups. This novel workflow can facilitate comprehensive cheminformatics analysis of materials, particularly complex carbon material systems.

PS-01 (1), Lecture Theater 3, august 28, 2024, 10:30 - 12:30

Background incl. aims
The isolation of graphene in 2004 raised an enormous excitement in the community, bringing to light a fundamentally new class of low-dimensional materials. Soon after, the graphene's insulating cousin – hexagonal boron nitride – was introduced, initiating a burst of papers speculating about a new electronics era. Process scalability, which is necessary for the utilization of 2D materials on a larger scale, excludes the mechanical exfoliation and significantly narrows the choice of suitable growth techniques. In this regard, the most promising approach is that of chemical vapour deposition (CVD), in which the precursors are delivered from a gas phase to the substrate, where they react and form the growing layer. However, in contrast to exfoliated layers, those prepared by CVD exhibit a significantly higher concentration of various structural defects, which are detrimental to many quantum effects and device functionalities the physicists and engineers search for. The defect family in 2D materials includes domain boundaries (GBs) and twin defects, together with many types of vacancies and anti-sites. GBs were identified to play a critical role in many aspects. The mitigation strategies include specific sample preparation techniques or the use of single-crystal substrates. Developing a more general strategy to avoid the formation of GBs within a footstep of the intended 2D-material-based device (and, preferably, at a wafer-scale) is desirable. Rheotaxy (growth on a liquid substrate) has been proposed as a viable method to achieve domain ordering and self-assembly already in 2012 for graphene [1]. However, it remains poorly explored due to a lack of in-situ experimental techniques that confirm or disprove hypotheses raised concerning the formation mechanisms [2]. Only recently, experimental studies started to pop-out [3].

Methods
We have utilized two modified microscopes for observing the graphene growth on liquid : a microReactor [4] in SEM and ultrahigh vacuum SEM. We observe graphene growth behaviour in situ, allowing to record movies of graphene flake behaviour on liquid gold and copper. We combine our electron microscopy observations with in situ atomic force microscopy (AFM) measurement of the contact angle of graphene on liquid gold, together with ex situ Raman characterization of the final graphene layer.

Results
We have been able to demonstrate some aspects of the graphene growth on liquid substrate, that have been hypothesized so far, namely movement and ordering of the graphene flakes on liquid surface (Cu and Au), via real-time movies under various reaction conditions. The flakes seem to assemble into regular patterns on liquid surface, however, this pattern is prone to disturbances, caused by e.g. hydrodynamics of the liquid (Fig. 1). Additionally, we obtained kinetic data of graphene growth, allowing us to directly compare solid and liquid growth rates. These data show significant increase of reaction constants on liquid metal. Last, we will show in situ AFM data,

discussing the possible presence of meniscus between the graphene flake and the liquid metal. Altogether, we frame these observations within a simple physical model.
Fig.1 shows behavior of graphene islands on undercooled liquid gold captured by the SEM, at temperature 1040 °C and C2H4/H2 partial pressure of 40 Pa. The movement is oscillatory (a) and the islands rotate and align with respect each other, which causes the distortion of the image and appearance of “vibrations” because of the scanning beam. Coalescence happens slowly, except for cases when the islands’ distances decrease below a certain value or after stimuli such as solidification (b). The scale bar is 1 µm.

Conclusion
In this contribution, we will show a quantitative analysis of in situ experimental data of graphene flakes assembly on liquid metal under growth reaction conditions. We combine in situ electron microscopy in different vacuum environments at extreme temperature with atomic force microscopy to show that the choice of the liquid metal is vital for achieving regular assembly of graphene and seamless stitching. We corroborate experimental observations with simple physical models of 2D solids floating on a liquid surface and explore weak-points of the synthesis, giving directions for further research towards scalable growth of 2D materials.

Background
A common feature among positive strand viruses is that they alter cellular membranes to generate replication complexes. Although the origin, nature and structure of these membranous compartments are not identical, they constitute a characteristic feature of these viruses and are observed in yeast, plants and higher eukaryote (+)-strand RNA viruses (3).
HCV infection provokes a rearrangement of intracellular membranes, designated membranous web (MW). This term referred to compact vesicle accumulations embedded into a membranous matrix (2).
In SARS-CoV-2, the expression of the viral proteins results also in a profound remodeling of the infected cell cytoplasm, with the characteristic membranous compartment, generically denominated viral replication organelle (VRO). One of the salient characteristics of the coronavirus VRO is the presence of double-membrane vesicles (DMVs), where various nsp and double-stranded RNA (dsRNA) have been shown to colocalize and where active RNA-dependent RNA synthesis has been shown to occur. Thus, DMVs are the structures where coronavirus RNA replication is thought to occur. While the nature and origin of the membranes may differ, DMVs are also the putative RNA replication organelle for hepatitis C virus (HCV).
In our research we study the morphology of the membranous rearrangements induced by HCV and SARS-CoV-2 infection in near-native conditions (1).
These infection alterations in HCV could be reverted by the clinically approved direct-acting antivirals (DAAs) for the treatment of chronic HCV infection. The availability of DAA drugs against HCV provides a unique opportunity to revert this process and to define the ultrastructural events that follow viral replication blockade short after antiviral treatment (4).

Methods
In this study we have performed infrared microscopy, confocal immunofluorescence and correlative cryogenic light-soft X-ray tomography (CLXT) in the water window photon energy range to investigate in whole, unstained cells, the morphology of the membranous rearrangements induced by HCV and SARS-CoV-2 infection and after antiviral treatments in near-native conditions.

Results
Our results compare the HCV and SARS-CoV2 replicating structures. SARS-CoV-2 infected cells display DMV structures similar to those found in other coronaviruses or hepatitis C virus infection. Our studies provide a wider cellular context in which these membranous alterations occur and point at the formation of compact perinuclear structures where viral antigens are concentrated by constriction within intermediate filaments, as determined by confocal microscopy. This perinuclear structure is formed by a tightly juxtaposed tubular membranous network reminiscent of a highly modified endoplasmic reticulum. This structure is virtually devoid of normal mitochondria and

adjacent mitochondria display clear ultrastructural signs of stress. Finally, late stages of the infection indicate deformation of the cell nucleus in areas close to the viral factory and an overall cytoplasmic retraction of the infected cell.
Analysis of DAA-treated HCV replicons indicate that most viral antigens and RNA are eliminated within the first 48 hours of treatment. CLXT studies confirmed the rapid elimination of the viral machinery, and the concurrent appearance of large endo-lysosomes and multivesicular bodies, suggesting a major role for this recycling machinery in the elimination of HCV-induced membranous compartments (5). A general survey of control cells and HCV replicons indicates that HCV-induced membranous alterations are no longer visible after 24 hours of treatment and that a substantial fraction of NS5A, a viral component of the replicase is located in pleomorphic, high-absorption contrast organelles in DAA-treated cells.

Conclusions
Overall, our cryo-SXT data provide an additional piece of the puzzle in building a precise map of the ultrastructure of SARS-CoV-2-infected cells by providing insight into the overall structure of the viral replication organelle and the cellular context within which these changes occur.
Our results suggest that HCV replication compartment is constantly recycled by the endo-lysosomal system and that this equilibrium is unbalanced by DAA treatment, resulting in a transient activation of the endo-lysosomal system to achieve rapid viral machinery removal. Our results also constitute a proof of concept for the use of cryo-SXT at ALBA synchrotron and at lab-scale soft X-ray microscope (SXM) as a platform that enables determining the potential impact of candidate compounds on the ultrastructure of the cell that may assist drug development at a preclinical level.

Effect of the Applied Chemical Potential on Strong Metal-Support Interaction in Ni-TiO2 Catalysts

Min Tang[1], Matteo Monai[2], Angela Melcherts[2], Kellie Jenkinson[1], Bert Weckhuysen[2], Sara Bals[1]
[1]EMAT and NANOlab Center of Excellence, University of Antwerp, Antwerp, Belgium, [2]Inorganic Chemistry and Catalysis group, Institute for Sustainable and Circular Chemistry and Debye Institute for Nanomaterials Science, Utrecht University, Utrecht, Netherlands

PS-05 (1), Lecture Theater 1, august 28, 2024, 10:30 - 12:30

Background incl. aims
Strong metal–support interaction (SMSI) refers to metal nanoparticle coverage by suboxides that are generated from the support under reducing conditions. SMSI may serve as a powerful tool to tune the activity, selectivity, and stability of a catalyst in diverse reactions. Since the pioneering work of Tauster et al. on SMSI in Pt group nanoparticles (NPs) supported on a TiO2 support,1 there have been plenty of studies about SMSI for different catalyst systems, pretreatments and conditions. Recent studies showed that SMSI depends on many parameters, such as temperature and gas composition. For example, Matsubu et al. found that after treatment in 5% H2/N2 at 550 °C for 10 min, a TiOx SMSI crystalline bilayer was formed for Rh-TiO2, while after treatment in 20CO2:2H2 at 250 °C for 3 h, an amorphous SMSI overlayer was induced.2 Frey and co-workers reported that SMSI-induced encapsulation of Pt-TiO2 observed under reducing conditions is lost once the system is exposed to a redox-reactive environment containing O2 and H2.3 Very recently, Monai et al. found that thin TiOx bilayers formed on 111 facets of Ni-TiO2 catalysts during 400 °C reduction, which were completely removed under 1CO2:3H2. Conversely, after 600 °C reduction, the amorphous TiOx overlayers was only partially removed under 1CO2:3H2.4 It is currently still unknown how overlayers evolve with temperature. Moreover, it is yet to be studied systematically how the applied chemical potential affects the SMSI. Herein, through in situ ambient pressure TEM, we studied the effect of the applied chemical potential, including partial pressure of H2, temperature, and temperature rate, on SMSI in Ni-TiO2 catalyst systems.

Methods
Ni catalysts supported on TiO2 (Degussa P25, S.A. = 60 m2/g) were prepared by homogeneous deposition precipitation (HDP) with urea. The system was kept at 95 °C for 20 h under vigorous stirring to induce Ni precipitation via the hydrolysis of urea. Then, the system was washed by centrifugation with water until the pH of the supernatant was neutral. The resulting powders were dried at 60 °C overnight, followed by further drying at 120 °C for 24 h. In situ scanning transmission electron microscopy (STEM) studies were carried out using an aberration-corrected ThermoFisher Scientific Titan Cubed electron microscope operating at 300 kV. The gas and heating nanoreactor comprised two electron-transparent Si3N4 windowed chips and a gas cell holder (climate G+, DENSsolutions). The prepared powder Ni(OH)x/TiO2 was dispersed in ethanol and deposited on the lower climate chip before constructing the climate holder and sealing the nanoreactor. The reduction was performed for 4 h in a 5% H2/He, 50%H2/He or 100% H2 at 400 °C and following the increasing temperature step by step to 600 °C.

Results
The reduction process in 5% H2/Ar is shown in Figure 1a-c. Almost no changes were observed after more than 3 h reduction at 400 °C. When the temperature was raised to 600 °C and held for 48 min,

Ni(OH)x was reduced to Ni (as shown in the red dashed square in Figure 1c). Some of the TiO2 support decomposed to small TiOx NPs. Figure 1d-f showed the reduction in 50% H2/He. Ni NPs were obvious at 400 °C only for 37 min. At 600 °C, the Ni NPs sintered significantly and the TiO2 support was not stable (marked by red dashed square in Figure 1f). These results indicate the importance of the partial pressure of H2 during the reduction and SMSI formation in supported Ni catalysts. Atomic resolution HAADF-STEM images are shown in Figure 1g-j. As we increased the temperature step by step from 400 °C to 600 °C, TiOx bilayers survived at even 600 °C. These results demonstrated that the temperature ramp also has significant effect on the structure of SMSI layers in Ni-TiO2.

Conclusions

Using in situ ambient STEM, we studied the effect of the applied chemical potential, including partial pressure of H2, temperature, and temperature rate, on SMSI in Ni-TiO2 catalyst systems. We found that partial pressure of H2 affects the reduction of Ni(OH)x and the type of the SMSI encapsulation. Although SMSI bilayers survived with temperature increasing, Ni NPs still sintered.

PS-08 (1), Lecture Theater 2, august 27, 2024, 10:30 - 12:30

Background
In the pursuit of neuromorphic computing, which seeks to emulate the human brain's intricate computational capabilities, the transition of digital memory to an analogue state is crucial. A central scientific question revolves around directing materials to incorporate synaptic plasticity. Among the most promising and technologically advanced strategies for achieving this are resistive random access memory (ReRAM) devices. Traditional ReRAMs operate through the stochastic formation and breakage of conductive filaments within an insulator storage medium, making control challenging. By deliberately introducing an A-site cation (Sr) deficiency in $SrTiO_3$ of up to about 16% through metal organic vapor phase epitaxy (MOVPE), we have successfully realized resistive switching without the need for filament formation, achieving on/off ratios as high as 10^3 [1].
In this study, we integrated various techniques of in situ scanning transmission electron microscopy, including differential phase contrast (DPC) imaging, integrated-DPC imaging, energy-dispersive X-ray spectroscopy (EDS), electron energy-loss spectroscopy (EELS), precession electron diffraction, along with I-V curve measurements. This comprehensive approach enabled us to gain insights into the underlying mechanisms and holds potential for developing more controllable memristive materials for ReRAM devices.
Methods
The theoretical crystal and electronic structures were calculated by the Heyd-Scuseria-Ernzerhof (HSE) hybrid functional method within density functional theory (DFT). The STEM simulations were performed with the structure concluded from the HSE calculations and with the simulation code adapted from Kirkland[2]. The high-resolution STEM imaging and spectroscopy were acquired from a probe-corrected Thermo Fisher Scientific Spectra Ultra operated at 300 kV, while the precession-assisted 4D STEM were obtained on Tescan Tensor STEM operated at 100 kV.
Results
As shown in the figure, a reversible switching of electrical field direction was observed from iDPC and DPC imaging of the off-stoichiometric $SrTiO_3$ TEM sample upon in situ switching between positive to negative bias. Reducing the voltage to 0 V results in a stable state, albeit with the polarization erased, returning the local film to a high-resistance state. The results from EDS and EELS mapping tells that approximately 16% of the Vsr sites are occupied by Ti. The observed resistive switching phenomena can be attributed to trap-assisted tunneling through Ti antisite defects, which induce a switchable polarization characterized by negative spherical aberration imaging (NCSI).
Additional details, including scanning precession electron diffraction, which maps nanoscale strain and electric field with high precision, EELS mapping, which discerns different valence states of Ti, and a few others, will be presented on site.
Conclusion

The correlation between structure, composition, bias and electric field distribution from in situ STEM biasing experiments gives direct evidence of antisite defects induced memristive switching in the off-stochiometric $SrTiO_3$ sample. The findings offer bottom-up perspective on the promising prospects for future neuromorphic computing applications. The workflow presented here facilitates new insights in developing similar materials.

Unlocking 3D nanoparticle shapes from 2D HRTEM images: a Deep Learning breakthrough

Romain Moreau[1], Dr. Hakim Amara[1], Dr. Maxime Moreaud[2], Dr. Jaysen Nelayah[3], Mr. Adrien Moncomble[3], Dr. Damien Alloyeau[3], Pr. Christian Ricolleau[3], Dr. Riccardo Gatti[1]

Poster Group 2

Background incl. aims
Nanoparticles (NPs) are typically observed and analysed using High Resolution Transmission Electron Microscopy (HRTEM) for highly precise structural studies at the atomic scale. However, determining their 3D shapes from 2D HRTEM images is a tedious process. Indeed, this type of analysis is based on manual post-processing which suffers, among other issues, from experimental noise or human bias performed at post-experimental stage. In this context, the integration of artificial intelligence (AI) methodologies into data acquisition and analysis protocols is a very promising approach [1]. To tackle the problem of identifying the 3D shape of NPs, we developed a Deep Learning (DL) model to automate this task ensuring reliable statistical analysis of a large number of NPs many of which cannot be identified by conventional methods.
Methods
For this purpose, we extend an approach we had developed to identify the structure of carbon nanotubes from their Moiré patterns obtained from HRTEM images [2]. More precisely, the DL model, leveraging Convolutional Neural Networks (CNNs), is trained on datasets of simulated HRTEM images of NPs, labelled according to their shapes, ranging from 4 to 8 nm. A critical point of this study was generating a representative and optimised dataset. To accomplish this, we constructed atomistic 3D models of NPs deposited on an amorphous carbon substrate, subjecting NPs to random rotations to encompass all potential observed orientations. Furthermore, we simulated the amorphous substrate using realistic carbon membrane derived from a tight-binding framework and noise models, to mimic experimental conditions [3]. Finally, HRTEM images were simulated using the Dr Probe code [4] based on the multi-slice method with parameters consistent with aberration-corrected transmission electron microscopes.
Results
The objective of generating an optimal training dataset was attained through comprehensive studies evaluating the impact of various parameters, including amorphous carbon, resolution, focusing conditions, NPs' size, and NPs' orientations, on DL model predictive accuracy.
Conclusion
This approach has resulted in the development of an efficient and accurate DL framework for predicting 3D NP shapes from 2D HRTEM images, validated across both simulated and experimental datasets (see figure).

Irbis: Software for 3D reconstruction and temporal analysis of 4D microscopy data

Stepan Kortus[1], Iva Svecova[1]
[1]The Institute of Experimental Medicine CAS, Prague, Czech Republic

Poster Group 2

Background:
Irbis is a newly developed software aimed at analyzing 3D and 4D microscopy image data. It is particularly useful for live-cell super-resolution microscopy experiments, enabling users to accurately reconstruct structural details, segment the model into relevant substructures and monitor those over time. The primary focus of Irbis is on the analysis of dendritic spines, although it seeks to be applicable to a wider range of biological structures in future developments.
Methods:
The software puts emphasis on multimodality with three main data types supported: bitmap images (such as confocal z-stacks), localizations (from single molecule localization microscopy experiments) and trajectories (from single molecule tracking experiments). The raw data is transformed into a 3D model, segmented, and the objects are subsequently registered in time so that their temporal development can be studied.
To transform raw data into a 3D model, Irbis uses Marching Cube (1) and Poisson surface reconstruction (2) algorithms. The primary model is subsequently segmented into individual substructures. The segmentation of dendritic spines is performed via a customized process that begins with solving the shortest path problem to identify the dendrite's center line, followed by the creation of the dendritic shaft's 3D outline using an adjusted active contour algorithm. This structure is then used to separate the protruding spines from the centre of the dendrite.
Results:
Irbis produces detailed 3D models from the analyzed data. It enables identification and analysis of substructures, such as synaptic spines, over time. Moreover, if more channels with different structures are present in the microscopy data, the dynamics of these structures can be related to each other. This can be used, for example, to study the behavior of synaptic signal relative to the structural information from dendritic spines.
Conclusions:
Irbis contributes to the field of microscopy image analysis by offering a tool that supports detailed 3D reconstruction and the temporal analysis of biological structures. While it currently focuses on dendritic spines, its methodology and features will be expanded for broader application in future development. Compared to other spine analysis tools, Irbis emphasizes accuracy in data reproduction and the analysis of structure development over time, within a user-friendly interface designed for accessibility to researchers without programming skills.

PS-03 (3), Lecture Theater 2, august 30, 2024, 14:00 - 16:00

Background incl. aims
Multiple quantum wells (MQW) and single quantum wells (SQW) of Ga(1-x)InxN on GaN are promising candidates for nanooptical light emitters due to their high quantum efficiency. The band gap of Ga(1-x)InxN can be controlled over a wide wavelength range by tailoring the variation of the indium concentration [1]. In addition, the epitaxially grown quantum well structures can be easily modified using chemical etching for the formation of a pyramid containing a quasi quantum dot structure. As the dimension of the quantum structure shrinks, the variation of the local indium concentration impairs the optical properties. Therefore, a robust characterization technique is required to understand and optimize such complex structures on the atomic scale.
Methods
In this study, an ultra-thin single quantum well of Ga(1-x)InxN between GaN layers on an Al2O3 substrate was grown using metal organic vapor phase epitaxy (Fig. 1). The cross-sectional specimen was prepared using focused ion beam, including the final low kV milling. The prepared specimen was characterized using a double-aberration corrected JEOL NeoARM 200F equipped with a cold field emission gun. For a precise intensity and local lattice parameter analysis, sequential high-angle annular dark-field (HAADF) imaging was utilized with a reasonably short acquisition time (1 sec/frame). The entire image stack was aligned by the rigid registration algorithm and averaged out to obtain a single drift-corrected HAADF image (Fig. 2(a)).
Results
The fractional intensity (normalized by the incident electron beam intensity) of the HAADF image was analyzed based on frozen phonon multi-slice calculation results [2]. The local thickness was determined by the mean intensity of the Ga atomic columns in the GaN layers and additionally verified by the acquired position averaged convergent beam electron diffraction (PACBED) pattern (Fig. 2(e,f)) [3]. The local indium concentration of the single quantum well of Ga(1-x)InxN was finally derived from the fractional intensity of the HAADF image (Fig. 2 (d)), showing the mean indium concentration of 13 at.% within the single quantum well. In addition, the local lattice parameters were analyzed based on the individual atomic column positions obtained from the drift-corrected HAADF image (Fig. 2(g)). The local indium concentration was then derived using a modified Vegard's law including biaxial elastic strain effects (Fig. 2(h)). The mean indium concentration within the single quantum well from this analysis was 10 at.%. This result was reasonably comparable with the local indium concentration obtained from the quantitative HAADF intensity analysis. Moreover, this local composition information was supported by the quantitative electron energy-loss (EEL) spectroscopy analysis at the unit cell level, confirming the mean indium concentration of about 16 at. % (Fig. 3).
Conclusion
The combination of HAADF imaging, PACBED, and spatially resolved EEL spectroscopy techniques provided detailed structural and chemical information of Ga(1-x)InxN quantum well structure. The

relationship between atomic structure and composition could be thoroughly studied. These robust combined scanning transmission electron microscopy (STEM) techniques will ultimately reveal the effect of altering indium concentration on complex quantum dot structures.

Gigabytes to Megabytes – Rapidly analyzing in-situ videos to track lattice spacing changes

Ben Miller[1], Cory Czarnik[1]
[1]Gatan, Inc., Pleasanton, USA

Poster Group 2

Background incl. aims
Recently, counted direct detection cameras which are virtually noise-free have enabled very faint diffraction spots to be detected at high spatial frequencies. These same cameras provide sharp detail, enabling spots to be precisely located. This combination of a large range and high resolution in reciprocal space requires large images to be captured. When samples are also changing over time, the capacity to capture an entire video dataset of the dynamic behavior is also valuable. This leads to three-dimensional datasets with billions of pixels that may be tens of gigabytes in size. These may be information-rich, but are impossible to visualize or analyze without some processing. In this work, we use a Python script to process each diffraction pattern in an in-situ video dataset to produce a series of radial profiles over time. This reduces the dimensionality, making them more amenable to visualization, easier to analyze, and significantly smaller. It also provides a more directly interpretable result in minutes that can be used to determine whether good data has been captured while the user is still sitting at the microscope.
Methods
The Python script used in this work processes each diffraction pattern in an in-situ video dataset to produce a series of radial profiles over time. It is freely available online[1] and runs within the Gatan DigitalMicrograph software, which facilitates immediate application of the processing to diffraction datasets just collected at the microscope. The script does not merely calculate a radial average, since this will tend to miss faint spots, especially those at large spatial frequency, where there may be thousands of pixels at a specified radius, but only a few with real diffraction signal. Even if the detector was perfect, contributing no noise to the pattern, shot noise from the diffuse scatter in the pattern at that radius would often contribute more to the average than the real signal. Instead the script calculates a radial maximum, and subtracts the radial average, reducing the impact of any uniformly distributed background intensity. It also masks the center of the pattern and optionally filters it with a median filter prior to calculating the profiles. The script applies this processing to every frame in an in-situ video dataset captured by a Gatan in-situ camera, and produces two equivalent outputs. The first output is a 1D profile over time, which can be played back with the same In-Situ Player used to play back the original data, and is automatically synced with the original data if this is also displayed. The second output, as shown in Figure 1, is a 2D visualization where the horizontal axis is time, and the profiles are displayed vertically with the center of each pattern at the top. While this abstract is focused on the application of this script to diffraction patterns, it should be noted that a similar approach can be applied to high resolution TEM videos by first computing the FFT of each frame.
Results
This script reduces the dimensionality of datasets from 3D to 2D, reducing data size and facilitating visualization and analysis. For a diffraction dataset with 1k x 1k patterns (1 million pixels) a single radial profile with minimal loss of resolution is 500 pixels, so the reduction in data size is roughly a factor of 2000. If the same dataset has 1,000 frames with a bit depth of 32, the data size will be reduced from around 3.7 GB to 1.9 MB. This takes about 3 minutes on the Gatan camera computer,

making it possible to run during a TEM session. In many cases, this can immediately inform the user about whether they've collected the data they need. For almost all datasets, it is easier and faster to perform further processing or analysis on the 2D data, rather than the full 3D dataset.
We have applied this diffraction processing to 2 classes of in-situ videos. First, this has been applied to monitor the damage of beam-sensitive materials over time, including metal-organic frameworks (MOFs) and zeolites. If the electron dose rate is known, this can rapidly quantify the amount of dose required to degrade or destroy the sample. Second, the same script has been applied to in-situ videos of reversible phase changes, making it easy to determine the exact timing of the phase change, and to correlate this with the in-situ conditions.
It should be noted that not all changes observed in diffraction patterns over time can be attributed to beam damage or phase changes. Sample drift in x-y or in the z direction, or rotation of small crystals can lead to changes in the pattern which are difficult to distinguish changes that are the result of more interesting phenomena. Care must be taken by the user to correctly interpret the changes observed, and a full discussion of this is outside the scope of this work.
Conclusions
In-situ diffraction data captured by modern cameras is information-rich, but can also be very large and must be processed. Rapid processing and visualization can be performed using Python in DigitalMicrograph to reduce dimensionality and data size prior to performing detailed analysis. A freely available script has been written to perform this analysis, and applied to video datasets of beam damage and phase transformations.

Figure: Examples of 2D visualizations of in-situ diffraction datasets. For each dataset, the profiles go from the center of the pattern at the top toward the edge of the pattern at the bottom. Left: Datasets recording the effects of beam damage for 2D MOF-2 and for ZSM-5. The MOF sample was damaged in seconds, while the zeolite dataset was recorded for over an hour. Right: Datasets recording temperature-induced reversible phase transformations: Sn nanoparticles being heated repeatedly above and below the melting point, VO2 heated above and below its metal-to-insulator transition, with varying ramp rates.

Background
Over the last 20 years, in situ (scanning) transmission electron microscopy [(S)TEM] has become an established experimental technique, driving innovation in material design and supporting new applications-based research strategies [1]. Its unique combination of ultra-high resolution imaging/analysis and relevant in situ sample environments has opened a new window into understanding material performance and degradation over time [2-3]. The goal of in situ TEM research is understanding the relationship between the structure of a material and its resulting function. Once commercial in situ TEM systems became available, a new set of experimental challenges revealed themselves: creating reproducible sample preparation that does not alter material behavior, understanding how to properly scale an experiment from bulk to nanoscale, keeping accurate records of the tens or hundreds of changing parameters utilized during an experiment, understanding electron beam effects, and managing/visualization of large amounts of data. While the ability for the in situ TEM system to produce pertinent environmental conditions is incredibly important to the relevance of the results, it is equally important to have a reliable means of streamlining all steps of the experimental workflow surrounding the in situ TEM experiment itself. Here we describe recent advancements supporting the entire in situ TEM workflow, from sample preparation to in situ conditions to data publication, that increase the reproducibility and relevance of the results while also providing compliance with FAIR principles [4]. Examples to be discussed are related to the global push for more efficient, cost-effective, and environmentally friendly means of energy storage and generation: batteries, electrocatalyst, and nanomaterial chemistry and growth.
Methods
All results discussed use Protochips in situ TEM solutions equipped with AXON machine vision software. Protochips in situ solutions are flexibly designed to create the most relevant in situ environments for a variety of materials in different research areas while being optimized for important analytical techniques such as EDX, EELS, iDPC, 4D-STEM, and others. Sample supports are MEMS-based silicon chips, called E-chips, that are designed and fabricated in-house at Protochips with input from scientific experts in the community. Functional measurements are done with high-sensitivity, low-noise potentiostats and highly sensitive source measuring units (SMUs). Liquid-phase electrochemical experiments are performed with Poseidon AX Liquid Cell system and newly added capabilities will be shown, such as standard reference electrodes, flow management E-chips, and others. The electron beam is calibrated and dose/dose rate are measured and recorded using the AXON Dose module. Stabilization of dynamic samples is done live with automated physical drift correction from the AXON Synchronicity module. Visualization and export of results are done offline with the AXON Studio module.
Results
Data from a wide array of research areas such as liquid-based batteries, electrocatalysts, nanomaterial synthesis chemistry, and corrosion will be discussed. The in situ TEM workflow involves

multiple different facets: sample preparation onto E-chips, experiment optimization outside the TEM, data collection of dynamic materials, production of in-situ conditions that are relevant to the material's operational or native environment, and alignment of structural data (TEM) with functional data (mass spectrometry, cyclic voltammetry, etc.) for trend identification (Fig. 1). Each part of the integrated workflow will be discussed, describing the recent innovations that support proper scaling from bulk to nanoscale, accelerating productivity in and outside the lab, and fostering collaboration and discovery with local and global collaborators. Utilizing these new innovations will significantly improve experimental reproducibility, strengthen the relevance of results to applications-focused communities and enable more publications in application-specific journals, as well as lower the learning curve to in situ TEM for new researchers.

Conclusions

In situ TEM is clearly gaining traction as an important technique for application-focused research strategies alongside traditional bulk, macro, and mesoscale techniques. Relevant in situ TEM results can provide the most direct window towards innovations for improved materials. Increasing the relevance of the results not only lies in creating new environmental capabilities and in situ stimuli, but in innovations for all the steps involved in the scientific workflow. From reproducible sample preparation to data management and visualization, the entirety of the workflow needs to be considered when planning for and incorporating in situ TEM into applications-based research.

IM-12, Lecture Theater 5, august 26, 2024, 10:30 - 12:30

Volume electron microscopy is the only technique to date that provides both sufficient resolution (<20 nm) and sufficient field of view (>100 µm) for the dense reconstruction of neuronal wiring diagrams. Currently, there exist two systems that have already delivered mm³-sized synaptic resolution electron microscopy stacks: Multi-beam scanning electron microscopy [1, 2] (mSEM) and Gridtape-based automated transmission electron microscopy [3, 4] (Gridtape-TEM). Both techniques currently rely on collecting and imaging thousands of ultrathin serial sections (30 - 40 nm) being cut with a diamond knife on an ultramicrotome and collected on a tape, silicon wafer or gridtape. However, serial collection of ultrathin sections is delicate and inherently prone to failures and artefacts such as section loss, folds, cracks or knife marks. More than 50% of the errors of today's state-of-the-art automated neuron segmentation algorithms can be attributed to missing information due to serial sectioning. Consequently, more than 40 hours of manual segmentation proofreading by human experts are currently required to reconstruct a single cortical pyramidal cell accurately.

Gas Cluster Ion Beam Scanning Electron Microscopy (GCIB-SEM) [5] and Broad Ion Beam Scanning Electron Microscopy (BIB-SEM) [6] methods have been proposed to address the section loss issue. These methods involve the collection of thicker sections, in a range of 100-10000 nm in thickness, onto a silicon wafer, offering a more robust approach for section collection. The collected volume is then iteratively sub-milled using either GCIB or BIB techniques to match the desired resolution in the Z-axis and then imaged using an SEM.

Here, we adopt the same principle of collecting semi-thin sections with subsequent sub-milling and, to have an imaging time advantage, we propose using a commercially available multi-beam scanning transmission electron microscope - mSTEM (FAST-EM Delmic, Netherlands), and use BIB for iterative sub-milling. We will refer to the combination of the two as BIB-mSTEM. In contrast to mSEM, mSTEM forms the image from high-energy transmitted electrons that are much less sensitive to local electromagnetic fields and milling-induced irregular surface topography than low-energy secondary electrons. Additionally, mSTEM offers the advantage of being more cost-effective compared to mSEM, making it an attractive option for large-scale imaging projects.

As proof of the method, we first collected serial sections of 250 nm thickness directly onto a scintillator plate using the commercially available ultramicrotome (Leica, Germany). Subsequently, we iteratively imaged the sections with FAST-EM and sub-milled the volume using BIB, producing a series of iteratively milled TEM projection images for each section. We then used those projections to computationally reconstruct a high-resolution 3D stack of each section. We used a deconvolution

procedure to reconstruct or deconvolve virtual reslices (Fig. 1B+D) from the series of projection images (Fig. 1A+C). The data shows that the proposed method increases the Z-resolution sufficiently to capture small changes in the ultrastructural appearance of neurites, mitochondria and synaptic vesicles (Fig. 1D) [7].

Fig. 1: Data from an iteratively BIB-milled and FAST-EM imaged 250 nm thick section. A STEM projection images of the iteratively milled section. B Corresponding deconvolved/reconstructed slices. C, D Zoom-in onto a dendrite in A and B, respectively. Scale bar = 1 µm.

Background
Emerging volume electron microscopy (vEM) techniques are providing unprecedented insights into the nanoscale 3D structure of biological specimens. However, the limited sustained throughput of electron microscopes hinders large sample handling (1). Multiple approaches, including camera-array transmission EM, beam-deflection transmission EM and multibeam scanning EM, have been developed to improve throughput and are now delivering first results (2, 3). We present a workflow for multibeam volume microscopy, FAST-EM array tomography. FAST-EM is a commercial multibeam scanning transmission electron microscope which speeds up acquisition by scanning the sample with 64 beams in parallel (4).

Methods
In FAST-EM array tomography, biological samples are prepared by chemical fixation, heavy metal staining, dehydration and resin embedding (Figure 1A). Serial sections are produced by ultramicrotomy and deposited on a cerium-doped yttrium aluminum garnet (ce:YAG) scintillator crystal, coated with molybdenum. FAST-EM employs optical scanning transmission electron detection (OSTEM), where transmitted electrons are converted into photons by the scintillator, which are then collected and descanned onto a detector array. The sections are imaged sequentially using stage translations. The volume is reconstructed from 2D images by finding point-pair correspondences in the overlap region between individual images. The 3D reconstructed data is then segmented using manual or automatic techniques, after which data analysis is conducted.

Results
Several biological samples, including cultured cells, organoids, as well as tissue samples were imaged with FAST-EM. To demonstrate the workflow, a 265.000 um3 volume of ~70 cultured MCF-7 cells was reconstructed from 72 100nm thin serial sections resolving the mitochondrial cristae and membrane structures (Figure 1B). The data quality and alignment is consistent throughout the volume (Figure 1C-D). To further demonstrate the applicability of analysis tools developed for other electron detection techniques to FAST-EM and OSTEM detection data, all mitochondria were automatically segmented using MitoNet, a convolutional neural network for 3D segmentation (5). MitoNet applied to FAST-EM datasets demonstrated performance metrics similar to benchmark datasets obtained using other vEM modalities.

Conclusion
We implemented a workflow for multibeam volume transmission electron microscopy capable of imaging large regions of interest with feasible acquisition times, while providing images with high

resolution and contrast. FAST-EM potentially expedites EM for comprehensive sample scanning and statistical analysis across multiple conditions. This creates opportunities for novel applications, such as examining the inter-cellular variability in a large population of cells. Further increase of throughput is possible by optimizing the signal generation and collection, reducing overhead and increasing system autonomy.

PS-03 (2), Lecture Theater 2, august 30, 2024, 10:30 - 12:30

Background
Amorphous semiconductors have ignited considerable interest in technological explorations owing to their distinctive electrical and optical properties stemming from their disordered structure and thermodynamic metastability. Thermal treatments have the potential to enhance or activate certain unique properties by reorganizing their atomic and electronic structures. Establishing precise correlations between thermal processes, structure evolutions, and electrical properties is essential for understanding fundamental mechanisms and achieving high-performance semiconductor materials. Gallium oxide (Ga2O3) is an advanced semiconductor material characterized by an exceptionally wide bandgap ranging from approximately 4.5 to 4.9 eV, depending on its concrete crystal phase and doping level. This wide gap renders Ga2O3 well-suited for high-power and high-frequency electronic devices.
Herein, we will present our in situ TEM work in this scenario by visualizing the atomic and electronic structure evolutions of amorphous Ga2O3 annealed in an O2 atmosphere.
Methods
High-quality morphous Ga2O3 films, ranging in thickness from 100 to 200 nm, were deposited on gas cell chips from Protochips using molecular beam epitaxy (MBE). Under the ambient pressure of an O2 environment, the as-grown films were heated from room temperature to 1000 °C at a heating rate from 1 to 1000 °C/s. Time series of selected area electron diffractions (SAED) and images were acquired with an image aberration-corrected TEM of FEI Titan 80-300 during the heating process. Furthermore, in situ STEM images and electron energy loss spectra (EELS) were collected on a probe aberration-corrected Thermo Fischer Spectra Ultra equipped with GIF Tridem 863 from Gatan to elucidate the atomic and band structure changes.
Results
Figure (a) and (b) depict the bright field (BF) TEM images and corresponding SAED patterns at four typical stages during the heating process of the amorphous Ga2O3 from room temperature to 1000 °C at a heating rate of 1 °C/s. Figure (c) were SAED patterns processed by CrysTBox software with background eliminated, direct beam removed, and intensity averaged. Gold and red arcs are superposed in SAED patterns to represent Debye-Scherrer rings referred to {hkl} reflections of the cubic spinel and monoclinic phases, respectively.
As shown in the figure, a circular cubic spinel phase of Ga2O3 (γ-Ga2O3) with a size of approximately 100 nm is formed at the initial stage. Subsequently, these structures evolve into dendritic morphology, accompanied by the generation of the monoclinic phase (β-Ga2O3) and finally undergoing a full transformation to a polycrystalline monoclinic phase.
This transition can be identified as a reconstructive disorder-to-order phase transition mediated by the exchange of cations to the next nearest neighbor sites, as shown in Figure (d). The figure provides

a schematic description of the atomic structural evolution and energy barriers needed to overcome for disordered to ordered phase transition upon heating [1].
Further results, such as the complete time-series of BF images and SAEDs, the in situ low loss EELS reveling the band gap shift, and more, will be presented on site.
Conclusion
Our in situ TEM work provides a correlated perspective on the thermal treatments, phase transformations, and band gap shifts involved in the pure Ga2O3. These findings have significant implications for understanding the fundamental mechanisms and are pivotal for the design and engineering of wide bandgap semiconductors in photoelectric applications.

Background: Metal halide perovskites (MHPs) are promising candidates for the next generation of optoelectronic and photovoltaic devices. This is mainly due to their wide-gamut emissions, high color purity (<35 nm spread) and remarkable photoluminescence quantum yield of more than 90%. However, their commercial application is still hindered by fast degradation under real conditions. The main cause of the CsPbI3 instability is its transformation from the black perovskite phase (photoactive) into the yellow non-perovskite (inactive) phase under ambient conditions, where water molecules decrease energy barriers of phase transition. Strategies towards more phase-stable CsPbI3 include interfaces, ligands as well as composition engineering. The last one is frequently associated with the formation of Ruddlesden-Popper (RP) planar defects, as shown for doped CsPbBr3. However, the underlying reasons and pathways of formation of the RP phase remain undiscovered. Therefore, the aim of this study is to understand how modification of CsPbI3 with Zn2+ and Cd2+ helps to prolong phase degradation by exploiting local techniques such as quantitative transmission electron microscopy (TEM) combined with molecular dynamics (MD) structure simulations.
Methods: In this work, we utilize different TEM techniques such as High Angle Annular Dark Field Scanning Transmission Electron Microscopy (HAADF-STEM), 4D STEM and Energy Dispersive X-ray Spectroscopy (EDX) under low-dose conditions to retrieve local structural changes which might explain stability improvement upon doping. These experimental investigations were complemented by quantitative analysis using StatSTEM software. Moreover, to demonstrate single-phase 3D structure as well as the structure of RP/perovskite interfaces, MD simulations were used along with TEM image simulations through the MULTEM software.
Results: Cd2+ and Zn2+ precursors were introduced into the reactive batch during hot-injection synthesis of CsPbI3 nanocrystals. As-prepared modified material contained ~2.1 at.% of Zn and ~2.5 at.% of Cd uniformly distributed along the nanocrystals. To understand the mechanism of nanocrystals degradation, a series of ex situ TEM experiments was performed for pristine and modified samples. It was established that the degradation pathway includes the agglomeration stage and the phase transformation. Here, both modified samples have demonstrated prolonged stability after agglomeration up to 5 days for Cd-containing and 10 days for Zn-containing CsPbI3. Ruddlesden-Popper planar defects in a specific configuration were identified for each modified sample by means of advanced electron microscopy. Using high-resolution EDX we showed that both transition metals are mainly distributed in these defects which are present along the diagonals of the square-like projection of the nanocrystals. Detailed analysis showed that Cd2+ doping results in ½ lattice shift in one direction, whereas Zn2+ doping provides ½ lattice shifts in two perpendicular directions. This difference can be ascribed to the ionic radii difference between Cd (1.09 Å) and Zn (0.88 Å). Combining these observations with molecular dynamic simulations, Zn2+ presumably occupies interstitial positions in RP regions with only changing Cs and I content slightly to balance the charges, whereas Cd substitutes Pb atoms. Moreover, the RP phases include CsI layers of different

length in-between perovskite structure, providing a smooth transition from RP into the gamma-phase along [110]CsPbI3/[001]RP direction. The process of RP phase formation includes the drifting apart of neighboring [PbI6]4- octahedra as a result of strain in the lattice due to Zn and Cd incorporation. Afterwards, additional Cs and I atoms have to enter the created void, which is followed by a shift of the two perovskite parts in one or two directions for the Cd- or Zn-modified samples, respectively. We associate an improvement in phase stability for these materials with the presence of as-described RP defects. In the α-phase of CsPbI3 a corner-sharing structure is preserved with Pb-I-Pb bond angles of 180^o, while in a δ-phase the structure consists of edge-sharing [PbI6]4- octahedra with the Pb-I-Pb bond angles of 90^o. Hence, the smaller these angles are, the lower kinetic stability is, hence, black-to-yellow transformation occurs faster. According to MD simulations, the gamma-phase most likely has Pb-I-Pb bond angles of 152.7^o, while for the one-shifted RP phase, observed for Cd-modified material, the value equals to 154.2^o and for two-shifted RP phase, observed for Zn-modified material, the angle is 155.1^o. The observed tendency perfectly correlates with the phase stability test, where Zn-modified material demonstrated the highest stability in comparison to Cd-containing and unmodified sample, whereas Cd-containing sample also surpassed unmodified material. At the interface between RP/perovskite phases the angles are 154.5^o and 156.0^o for Zn and Cd-modified samples respectively, which also contributes to the enhanced phase stability.
Conclusions: We applied a combined experimental/theoretical approach to unravel the influence of modification with Zn2+ and Cd2+ on phase stability of CsPbI3 nanocrystals. From an experimental point of view, we were able to observe specific types of Ruddlesden-Popper (RP) phase defects across the nanocrystals, where Cd and Zn are mainly localized. These defects were analyzed in a quantitative manner using statistical parameter estimation theory applied to the TEM results. Combination of these experimental results with MD simulations reveals how the RP planar faults are formed in a presence of transition metals, where these atoms are positioned and explains how phase stability, as shown by series of ex situ TEM results, is related to these defects. This is why our study contributes to an enhanced understanding of mechanisms underlying perovskites stabilization and may foster its commercialization for further use in devices.

Continuous EELS spectrum imaging of nano-droplet crystallization heterogeneity

Ben Miller[1], Cory Czarnik[1]
[1]Gatan, Inc., Pleasanton, USA

Poster Group 1

Background incl. aims
Electron energy loss spectroscopy (EELS) is a powerful technique for characterizing nanomaterials; a number of materials properties can be extracted from the information-rich spectra. One application is nano-thermometry, where the local temperature of individual metal nanoparticles can be measured by a precise determination of the plasmon peak position [1]. As thermal expansion increases a particle's volume, the density of electrons decreases, and the energy loss of the plasmon peak shifts to lower energies. This same approach can be used to detect melting and crystallization, which result in even larger changes in the electron density. Continuous acquisition of EELS data enables precise determination of the melting and crystallization temperatures of individual particles. Using the new in-situ EELS spectrum imaging features of the Continuum GIF, a continuous series of drift-corrected spectrum images can be acquired over an ensemble of particles, and the melting and crystallization behavior of each one independently monitored. This would be more difficult or impossible with other techniques such as TEM imaging, diffraction, or 4DSTEM.
Methods
In this work, we show how a series of EELS spectrum images can be acquired and processed along with the temperature data from a MEMS-based heating holder from DENSsolutions. With modern fast detectors and spectrometers, spectrum images with thousands of spectra can be acquired in less than a second, making continuous in-situ spectrum imaging feasible. The holder temperature data is automatically synchronized and correlated with EELS spectrum image data. We also show how the entire series of in-situ EELS spectrum images can be rapidly fit using the built-in NLLS tools in DigitalMicrograph, yielding series of synchronized fit maps, as seen in Figure 1. After summing the EELS spectra over a single nanoparticle, plots of the peak position over time can be generated, and even plotted against the nominal temperature from the holder in scatterplots in DigitalMicrograph. The plasmon peak position within each particle indicates whether the Sn is melted or crystallized at that time.
Results
This new in-situ EELS spectrum imaging capability has been applied to a Sn nanoparticle sample which was oscillated above and below its melting temperature with varying ramp rates. Spectrum images were recorded at a rate of 1 frame every 1.54 s (2000 spectra/s). Watching the maps of plasmon position over time reveals that while all the Sn particles crystallized during most cycles, and most particles crystallized during every observed cycle, some particles occasionally did not crystallize even though surrounding particles did. Images and 4D STEM maps of the particles after the in-situ recording do not indicate a clear difference between a particle that always crystallized and the particles that sometimes did not. Some variation could be the result of random chance, as the nucleation and growth of a crystalline nanoparticle from a nano-droplet is governed by both thermodynamics, which would indicate that the particles should all crystallize at the melting temperature, and kinetics, which stipulates that nucleation times for an ensemble will have some distribution. However, there are only 3 particles (of 11 in the field of view) which don't always re-

crystallize, and one of them remains melted during 4 cycles, which seems unlikely to be due only to random statistical fluctuations in nucleation time.
This behavior would be significantly more difficult to observe with TEM or STEM imaging, where the visibility of lattice fringes is dependent on the orientation of the nanoparticles. It would also be challenging with standard diffraction techniques, where the crystallinity of multiple particles could not be independently and simultaneously observed. Continuously acquired 4DSTEM could be used, but this requires more data to be stored, and the analysis is more complex, especially if there are other small crystallites (oxides, etc.) which overlap the droplets, as there are here.
Conclusions
This heterogeneous and stochastic behavior at the nanoscale can only be observed with high spatial and temporal resolution. In-situ electron microscopy, and specifically in-situ EELS spectrum imaging is an excellent technique for exploring these dynamics.

Figure 1: One frame from a screen-capture video showing playback of the in-situ EELS spectrum image dataset. A) Simultaneously acquired dark field STEM images. B) Maps of the plasmon peak position. Arrows indicate 2 particles which have failed to re-crystallize despite super-cooling them to 50 °C. C) Live fit of the zero loss peak and plasmon peaks from the red “picker tool” region indicated in A. D) In-Situ Player which plays back and synchronizes all displayed in-situ dataset components. E) Automatically acquired and synchronized temperature data from the DENSsolutions heating holder used to heat the Sn above and below its melting point of 232 °C.

Electron Channeling Contrast Imaging (ECCI) of Ion Battery Cathode Materials

Ph.d. Candidate Meysam Naghizadeh[1], Dr. Chisu Kim[2], Pr. Raynald Gauvin[1]
[1]Department of Mining and Materials Engineering, McGill University, Montréal, Canada, [2]Center of Excellence in Transportation Electrification and Energy Storage Hydro Québec, Varennes, Canada

Poster Group 1

The microstructural characterization of ion battery cathode materials is often studied by transmission electron microscope (TEM) due to its high spatial and angular resolution which enables precise analysis of the battery materials. However, TEM studies present several challenges that might hinder their suitability for numerous potential applications. The conventional processes of preparing thin foils for TEM analysis, such as twin jet electropolishing, are time consuming and expensive. Moreover, when high-energy electron beams interact with the specimen in TEM, the studied sample may experience damage through various mechanisms, including knock-on displacement, radiolysis, and heating, leading to changes in the microstructure and properties of materials, particularly those sensitive to beams [1,2]. Here, another interesting approach for bulk specimens is presented that offers both a high spatial resolution and a large field of view at relatively low accelerating voltages: the use of ECCI in a field emission scanning electron microscope (FESEM). ECCI is an imaging method that relies on the change of backscattered electron (BSE) intensity caused by differences in the angle between the incoming electron beam and the crystallographic orientation of the lattice planes in crystalline samples. When the incoming electrons are parallel (or very close to parallel) to the lattice planes, low BSE intensity and hence a darker area can be anticipated, while with the increase in the angle, higher intensity and a brighter area are expected. ECCI technique allows us to figure out how the specimen's crystallographic orientation changes, along with identifying features like grain boundaries and cracks, as well as individual lattice defects such as dislocations [3,4].
In this study, the microstructural evolution of two different layered Li-ion based (composed of secondary particles) and Na-ion based (composed of primary particles) cathode materials in their pristine state was investigated. High resolution secondary electron (SE) and ECC images were acquired with the use of Hitachi SU8000 dedicated FESEM at a relatively low accelerating voltage of 4 kV. For this purpose, cross-sectional samples were prepared using a Hitachi IM4000 ion milling machine.
Figures 1a and b show the SE and ECC cross-sectional images of a Li-ion based cathode polycrystalline secondary particle. The secondary particle comprises many single crystalline primary particles. Primary particles are simply like the 3-dimensional grains found in conventional polycrystalline metallic materials with different crystal orientations. As can be seen in Figures 1a and b, the primary particles cannot be well recognized in the SE image (Figure 1a), while in the ECC image they are completely clear with very well-defined grain boundaries thanks to the ECCI technique (Figure 1b). Furthermore, the imperfections between the primary particles such as voids and pores are more evident with sharp edges in the ECC image compared to the SE image.
The SE and ECC cross-sectional images of a Na-ion based cathode single crystalline primary particle are represented in Figures 1c and d. The SE image displays the primary particle with an irregular shape without any distinguished lattice features (Figure 1c). However, the ECC image depicts the same particle with two clearly visible features shown by yellow arrows: I) coincidence site lattice boundary (CSLB) and II) intragranular crack along the CSLB as a preferential site for crack initiation

(Figure 1d). In an earlier study by the authors [5], the presence of CSLBs in the same specimen has been shown with the aid of Hitachi SU9000 scanning transmission electron microscope (STEM). Conclusively, this work unraveled the unique role of ECCI technique as a perfect microanalysis tool for reasonably priced and rapid investigation of the cathode battery materials.

Figure 1. a) SE and b) ECC cross-sectional images of a Li-ion based cathode polycrystalline secondary particle. c) SE and d) ECC cross-sectional images of a Na-ion based cathode single crystalline primary particle.

Application of reinforcement learning to aid the alignment of an electron microscope

Richard Konstantin Jinschek[1], Dr. Mounib Bahri[2], Dr. Mario Gianni[3], Dr. Yao-Chun Shen[4], Dr. Nigel D. Browning[2,5]
[1]Distributed Algorithms Centre for Doctoral Training, University of Liverpool, Liverpool, UK, [2]Department of Mechanical, Materials and Aerospace Engineering, University of Liverpool, Liverpool, UK, [3]Department of Computer Science, University of Liverpool, Liverpool, UK, [4]Department of Electrical Engineering and Electronics, University of Liverpool, Liverpool, UK, [5]SenseAI Innovations Ltd., Brodie Tower, University of Liverpool, Liverpool, UK

Poster Group 2

Background incl. aims
In both SEM and TEM, the alignment process for each experiment is unique and not replicable. If not done well this also has major implications on the stability of the experiments and the quality of the obtained data regardless of the specimen or sampling technique. It requires days of diligent practice on a variety of electron microscopes in order to become an expert and be able to collect data with the highest possible resolution consistently across experiments.
A proposed solution to this skill barrier is a digital twin for an electron microscope, with the purpose being to make experiments more reproducible, efficient and improving the overall reliability and resilience of experiments [1]. The initial steps in this is to automate the alignment process, starting with the eucentric height using machine learning (ML) techniques.
Methods
The proposed method for finding the optimal eucentric height is reinforcement learning (RL), a subset of ML where an agent learns how to interact with an environment in order to make decisions. Using a q-learning function and a reward function the agent is able to determine the optimal action in order to achieve the correct z-height. For training an agent on images at different z-heights learning a q-table is sufficient due to the small and finite action space. However, for applications on a microscope, a deep-q-network (DQN) is required, which instead of knowing the possible rewards from a trained q-table estimates the rewards and works for larger action spaces [2].
Results
Initial tests on a small state space where the environment is defined as images taken at different z-heights with intervals of 2µm ranging from 0µm to 50µm (including the eucentric height), show that the agent is able to learn a q-table within 10000 iterations. With this initialized q-table the agent is able to find the image that was taken at the eucentric height instantaneously.
Conclusion
Preliminary tests indicate that reinforcement learning holds promise as a viable solution for automating the alignment process of an EM, potentially reducing the expertise needed to conduct experiments effectively and accurately.

IM-03 (3), Plenary, august 29, 2024, 10:30 - 12:30

Scanning Transmission Electron Microscopy (STEM) is used extensively to study the atomic structure of materials at the nanoscale. So far, the dominant method for atomic resolution imaging is annular dark-field STEM, enabled by modern electron optics and popular because of its incoherent atomic number contrast. Developments in detector technology have caused the widespread adoption of fast direct electron detectors, which allow collecting a 2D momentum space image at every position of a 2D real-space scan, motivating the name 4D-STEM. Such 4D-STEM datasets allow recovery of phase information, and the high number of intensity measurements allows us to fit ever more complex models to the scattering data, increasing dose efficiency, resolution, and imaging throughput. Modern reconstruction algorithms can recover partial coherence effects, probe positions, and three-dimensional information beyond the numerical aperture limit from a single 4D-STEM dataset. However, the obtainable depth resolution in these approaches is currently more than a factor of ten away from the atomic scale needed for de novo structure determination. This motivates the collection of tilt-series 4D-STEM measurements, which allow higher dose efficiency to reach the 3D atomic resolution regime than 3D imaging approaches based on ADF-STEM.
Here, we show a series of advancements in instrumentation and 4D-STEM reconstruction methods that allow the determination of 3D atomic structure from 4D-STEM measurements and extend the sensitivity and volume limits of electron microscopy.

Methods & Results
Fig. 1a) shows an experimental demonstration of ptychographic electron tomography. We reconstructed a complex hybrid structure of a ZrTe nanowire encapsulated in a double-walled carbon nanotube [10]. We then solved the complete atomic structure from this 3D reconstruction. The nanowire comprises three unique structural motifs: an elliptic curved 2D material composed of ZrTe5 units, Te-Te chains, and a previously unobserved ZrTe2 core structure. The ZrTe2 core structure is closely related to the ZrTe5 structure, with the longer bond-length Te atoms removed and the stacking slightly modified. We also performed DFT to verify the stability of the proposed atomic structure of this nanowire [1].
In this study, we used a fast linear method for initial reconstruction and aberration parameter estimation, followed by iterative single-slice reconstruction, including partial coherence, and finally, tomographic reconstruction.
By explicitly modeling dynamical scattering within the sample using multi-slice ptychography, the accessible volume in ptychographic tomography can be significantly expanded beyond the conventional depth of field limit for 3D imaging in STEM. This allows for the retention of 3D atomic resolution in larger volumes.

Fig. 1b) shows an experimental demonstration of a sequential reconstruction approach to multi-slice ptychographic tomography on a Co3O4 nanocube. Here, we reconstruct a volume of 18.2nm side length and break the depth of field limit by a factor of >3x. The bottom panel of Fig 1b) shows cuts through the 3D power spectrum of the reconstruction, indicating that a resolution of 2Å axial and 0.7Å lateral resolution has been reached.
Reconstructing the electrostatic potential in an end-to-end fashion directly from 4D-STEM data can further increase the coupling of the voxels in 3D space, allowing the recovery of missing wedge information. The reconstruction strategies developed above can be utilized to bootstrap all parameters of such an end-to-end reconstruction efficiently.

Conclusion
We have developed atomic resolution ptychographic electron tomography to solve 3D atomic structures containing light elements and spanning volumes larger than the depth of field. Future applications include the imaging of beam-sensitive polymers, hybrid organic-inorganic structures, battery materials, and biomolecules.

Cation Vacancies Regulate the Electron Spin Configuration of Cathode Catalytic Additives towards Robust Li-S Batteries

PhD JING YU[1,2], Mr. Andreu Cabot[2], Mr. Jordi Arbiol[1]
[1]Catalan Institute of Nanoscience and Nanotechnology (ICN2), Bellaterra, 08193, Spain, [2]Catalonia Institute for Energy Research（IREC）, Sant Adrià de Besòs, 08930 , Spain

PS-04 (1), Plenary, august 26, 2024, 10:30 - 12:30

Background
Lithium-sulfur batteries (LSBs) are promising energy storage devices due to their high theoretical energy density (2600 Wh kg-1), large specific capacity (1675 mAh g-1), potential cost-effectiveness, and environmental friendliness.[1] However, the commercialization of LSBs is limited by factors such as polysulfide migration, sluggish kinetics of the sulfur redox reaction (SRR), and poor electronic and ionic cathode conductivities.[2] The use of defect-engineered catalysts, with tunable surface chemistry and electronic properties, as cathode additives in LSBs is a promising strategy to accelerate the Li-S redox reactions and thus promote LSB performance. In contrast to earlier research that predominantly concentrated on how defects influence the electronic density of states, the present work explores the impact of defects in modulating electronic spins and how these changes in spin configuration influence the macroscopic adsorption properties and activity of the catalytic additive.
Methods
In this study, a defect engineering strategy was used to tune the electron spin state of an SRR electrocatalyst. This strategy was showcased by introducing controlled amounts of cation vacancies within ultrathin CoSe nanosheets through plasma etching. Atomic resolution aberration-corrected high-angle annular dark-field scanning transmission electron microscopy (AC-HAADF-STEM) was used to gain in-depth insights into the spatial distribution of Co vacancies. 3D atomic models were obtained by using Rhodius and the corresponding AC-HAADF-STEM image simulations obtained by using STEM-CELL software.[3-4] XRD, EXAFS, XPS, Raman spectroscopy, XMCD, DFT calculations, EPR, in situ XRD combined with electrochemical test were conducted.
Results
Vacancies were also indirectly evidenced by an increase of disorder and reduced lattice spacing, Co-Se bond length, and Se coordination number using XRD, HRTEM, EXAFS, XPS, and Raman spectroscopy. XANES and XPS spectroscopy further showed an increase in the average oxidation state of cobalt with the introduction of vacancies and EELS pointed to a higher occupation of Co 3d states in v-CoSe. Beyond modifying the structural parameters and electronic state occupation, the presence of vacancies resulted in a polarization of the 3d electron spins as evidenced by an increase in the intensity of the satellite peak in the Co 2p XPS spectra, a strong Co dichroism signal obtained by XMCD and magnetic measurements that confirmed a large moment per Co ion of 2.8 muB in v-CoSe. EPR spectroscopy further confirmed the generation of additional electrons with unpaired spins by the introduction of Co vacancies.
DFT calculations showed these spin-polarized unpaired electrons to be easily transferred from v-CoSe to polysulfide. Computational results showed that the d band center shifts toward the Fermi level with the introduction of vacancies, which involves that electrons are more prone to disperse in the high-spin configuration. The altered spin configuration results in a swift transferability of additional unpaired electrons to the polysulfide. DFT calculations also showed v-CoSe to have significantly higher lithium polysulfide adsorption energies and to decrease the polysulfide stability upon adsorption, thus enhancing both polysulfide adsorption and conversion activity. Besides,

computational results showed the modified spin configuration to result in a more favorable thermodynamic reduction process, particularly for the transition from soluble polysulfide to solid Li2S that showed a lower nucleation energy barrier.
Experimental measurements confirmed an enhanced adsorption of the lithium polysulfide on the v-CoSe surface. Symmetric cells showed v-CoSe to provide a low polarization voltage and sharper and more intense redox peaks. In situ XRD showed a very rapid and complete transformation of S8 and a high lithium polysulfide redox activity in v-CoSe. EIS analyses showed v-CoSe to be characterized by a low SRR activation energy, particularly for the liquid-solid conversion stage. Besides, the presence of vacancies resulted in promoted Li2S nucleation, reduced LSB polarization voltages, and higher Q2/Q1 ratios. v-CoSe cathodes not only demonstrated excellent electrocatalytic properties but also outstanding LSB electrochemical performance in terms of specific capacity, rate performance, and cycling stability, even at high sulfur loadings.
As a result, more uniform nucleation and growth of Li2S and an accelerated liquid-solid conversion in LSB cathodes are obtained. These translate into CoSe-based LSB cathodes exhibiting capacities up to 1089 mAh g-1 at 1C with 0.039% average capacity loss for 1500 cycles, and up to 5.2 mAh cm-2, with 0.16% decay per cycle after 200 cycles in high sulfur loading cells.
Conclusion
Overall, this study demonstrates the need for considering the electronic spin configuration in the design of electrocatalysts, particularly for developing robust LSBs. Thus, the spin engineering approach showcased here paves the way to the rational design of new generations of LSB cathodes based on defect-engineered SRR electrocatalysts, toward the development of a cost-effective LSB technology with market-ready potential.

In this study, a defect engineering strategy was used to tune the electron spin state of an SRR electrocatalyst. This strategy was showcased by introducing controlled amounts of cation vacancies within ultrathin CoSe nanosheets through plasma etching. Atomic resolution aberration-corrected high-angle annular dark-field scanning transmission electron microscopy (AC-HAADF-STEM) was used to gain in-depth insights into the spatial distribution of Co vacancies. 3D atomic models were obtained by using Rhodius and the corresponding AC-HAADF-STEM image simulations obtained by using STEM-CELL software.[3-4] XRD, EXAFS, XPS, Raman spectroscopy, XMCD, DFT calculations, EPR, in situ XRD combined with electrochemical test were conducted.
Results
Vacancies were also indirectly evidenced by an increase of disorder and reduced lattice spacing, Co-Se bond length, and Se coordination number using XRD, HRTEM, EXAFS, XPS, and Raman spectroscopy. XANES and XPS spectroscopy further showed an increase in the average oxidation state of cobalt with the introduction of vacancies and EELS pointed to a higher occupation of Co 3d states in v-CoSe. Beyond modifying the structural parameters and electronic state occupation, the presence of vacancies resulted in a polarization of the 3d electron spins as evidenced by an increase in the intensity of the satellite peak in the Co 2p XPS spectra, a strong Co dichroism signal obtained by XMCD and magnetic measurements that confirmed a large moment per Co ion of 2.8 muB in v-CoSe. EPR spectroscopy further confirmed the generation of additional electrons with unpaired spins by the introduction of Co vacancies.
DFT calculations showed these spin-polarized unpaired electrons to be easily transferred from v-CoSe to polysulfide. Computational results showed that the d band center shifts toward the Fermi level with the introduction of vacancies, which involves that electrons are more prone to disperse in the high-spin configuration. The altered spin configuration results in a swift transferability of additional unpaired electrons to the polysulfide. DFT calculations also showed v-CoSe to have significantly higher lithium polysulfide adsorption energies and to decrease the polysulfide stability upon adsorption, thus enhancing both polysulfide adsorption and conversion activity. Besides, computational results showed the modified spin configuration to result in a more favorable

thermodynamic reduction process, particularly for the transition from soluble polysulfide to solid Li2S that showed a lower nucleation energy barrier.
Experimental measurements confirmed an enhanced adsorption of the lithium polysulfide on the v-CoSe surface. Symmetric cells showed v-CoSe to provide a low polarization voltage and sharper and more intense redox peaks. In situ XRD showed a very rapid and complete transformation of S8 and a high lithium polysulfide redox activity in v-CoSe. EIS analyses showed v-CoSe to be characterized by a low SRR activation energy, particularly for the liquid-solid conversion stage. Besides, the presence of vacancies resulted in promoted Li2S nucleation, reduced LSB polarization voltages, and higher Q2/Q1 ratios. v-CoSe cathodes not only demonstrated excellent electrocatalytic properties but also outstanding LSB electrochemical performance in terms of specific capacity, rate performance, and cycling stability, even at high sulfur loadings.
As a result, more uniform nucleation and growth of Li2S and an accelerated liquid-solid conversion in LSB cathodes are obtained. These translate into CoSe-based LSB cathodes exhibiting capacities up to 1089 mAh g-1 at 1C with 0.039% average capacity loss for 1500 cycles, and up to 5.2 mAh cm-2, with 0.16% decay per cycle after 200 cycles in high sulfur loading cells.
Conclusion
Overall, this study demonstrates the need for considering the electronic spin configuration in the design of electrocatalysts, particularly for developing robust LSBs. Thus, the spin engineering approach showcased here paves the way to the rational design of new generations of LSB cathodes based on defect-engineered SRR electrocatalysts, toward the development of a cost-effective LSB technology with market-ready potential.

Poster Group 2

Scanning Transmission Electron Microscopy (STEM) is currently a reference technique for high spatial resolution imaging, with wide adoption in the characterization of material science samples and with growing use in life science studies. 4D-STEM [1] approach presents a more detailed recording of the electron scattering pattern using pixelated electron detectors and extends the imaging possibilities by combining the real-space scanning and reciprocal-space scattering components. Recent improvements in the direct electron detector technology allow 4D-STEM experiments at similar speeds to STEM imaging [2], and motivates its exploration as a possible substitute to conventional imaging.

This study addresses the information retrieval from 4D STEM datasets using virtual bright field imaging, parallax-corrected phase imaging, and ptychography reconstruction. Large fields-of-view (> 500 nm) of reference samples were measured with fast 4D-STEM (10 µs dwell time), moderate defocus (~100 nm), and scanning sampling between 0.3 and 2.4 nm/pixel. The 4D STEM datasets were processed with the open-source python-based py4DSTEM package [3, 4], including the preliminary assessment and subset selection by virtual STEM images. Defocused probe parallax imaging and a ptychographic gradient descent method were used to correct probe aberrations, particularly defocus. These methods resulted in reconstructed images with effective upsampling, due to the information retrieval from both real and reciprocal spaces.

While the 4D STEM reconstruction with a virtual BF approach resulted in an image with spatial resolution limited by either probe aberration or sampling, equivalent to conventional BF STEM imaging, both parallax-corrected phase imaging and ptychography reconstruction allowed for information retrieval down to lattice level (< 0.2 nm). The findings indicate that 4D STEM reconstruction methods can yield resolution beyond real-space sampling, possibly limited by the effective electron dose used in fast 4D STEM experiments. A current challenge is to extend and optimize these image reconstruction methods to recover resolution from the full field of view of such large-area scans. However, with the increasing efficiency and accessibility of 4D STEM data analysis, the calculation and display of (near-) real-time super-resolution images is foreseen.

Contrast Optimization Aided by Machine Learning Applied to Virtual 4D-STEM Images

Daniel Stroppa[1], Dr. Roberto dos Reis[2,3,4]
[1]DECTRIS, Baden-Daettwil, Switzerland, [2]Department of Materials Science and Engineering, Northwestern University, Evanston, USA, [3]Northwestern University Atomic and Nanoscale Characterization Experimental (NUANCE) Center, Evanston, USA, [4]International Institute for Nanotechnology, Northwestern University, Evanston, USA

IM-10 (3), Lecture Theater 5, august 30, 2024, 14:00 - 16:00

Scanning Transmission Electron Microscopy (STEM) has revolutionized imaging due to its high spatial resolution and easy interpretation due to varied contrast mechanisms, such as atomic number (Z) contrast at high-angle scattering and phase contrast from the bright-field disk. The enhanced flexibility in terms of scattering range detection in comparison with STEM is one of the reasons that led to the increased interest in 4D-STEM [1]. Supported by the recent evolution of pixelated detectors, 4D-STEM currently allows for the recording of the complete electron scattering range at speeds commensurate with traditional STEM experiments [2]. With the possibility of flexible reconstruction of virtual STEM images with arbitrary detector shapes, contrast optimization for sample regions with different scattering cross-sections is envisioned. This study delves into the optimization of contrast in virtual 4D-STEM images, employing both user-guided and machine-learning (ML) optimization approaches.

Reference samples from semiconductor devices and supported catalysts were measured with fast 4D-STEM under experimental conditions mirroring standard STEM imaging practices, with 1024x1024 scan positions and 10 us dwell time. The resultant datasets comprised 106 diffraction patterns with 96x96 pixels each, presenting a great challenge for manual contrast optimization due to the vast data volumes and nuanced contrast differences within the areas of the specimens. Figure 1 shows manual contrast optimization applied to virtual 4D-STEM images, serving as a foundational comparison point for our machine learning (ML)-aided methodology. The left panel reveals a virtual Bright Field (BF) STEM image, with an inset in the upper left corner illustrating a typical example of electron scattering and the application of a virtual mask overlay, highlighting the initial manual approach to contrast enhancement. The center panel demonstrates a virtual STEM image that has been collected utilizing an optimized annular mask, reflecting the outcomes of manual contrast optimization efforts. In the right panel, a line profile from these virtual images is presented, with indications of contrast levels, offering a quantitative perspective on the enhancements achieved through manual methods. This figure effectively sets a benchmark for the subsequent introduction of our ML-aided approach, illustrating the initial state of contrast optimization against which the improvements facilitated by automated, ML-driven processes can be measured. By providing a clear depiction of manual optimization efforts, Figure 1 underscores the necessity and impact of transitioning towards more sophisticated, automated methodologies for contrast enhancement in 4D-STEM imaging

In the current study, we develop an innovative computational framework designed to automate the enhancement of contrast in similar regions within 4D-STEM data. Our methodology integrates the advanced deep learning architecture, ResNet101 [3], for feature extraction, followed by Principal Component Analysis (PCA) for dimensionality reduction, and the application of hierarchical clustering techniques (Figure 2). The utilization of ResNet101, distinguished for its deep residual learning capabilities, is strategically chosen to adeptly capture the nuanced, hierarchical

features inherent in 4D-STEM datasets, which are pivotal for identifying similarities across various regions. The initial phase of our analysis involves processing the 4D-STEM diffraction patterns through the ResNet101 model, which has been pre-trained on extensive image datasets. This step is instrumental in extracting comprehensive high-dimensional feature vectors that encapsulate the essential attributes of each pattern. Such a transformation of raw diffraction data into a quantitative form surpasses traditional manual feature identification methods, which are often subjective and labor-intensive, by leveraging automated, objective feature extraction. Following feature extraction, we employ PCA to transform the high-dimensional feature space into a lower-dimensional one, effectively reducing the computational complexity while preserving the variance critical for subsequent analysis. This dimensionality reduction is crucial for enhancing the tractability and interpretability of the dataset, allowing for a focused examination of the significant variances among diffraction patterns. The analysis concludes with hierarchical clustering, an agglomerative method that iteratively merges data points based on their similarity, thereby organically identifying clusters of similar regions without the need for predefining the number of clusters. This method is selected for its adaptability in uncovering the inherent groupings within the data, thereby facilitating an intuitive understanding of similarities across the dataset. The dendrogram generated in this process serves as a pivotal tool for visually determining the grouping of similar regions, thereby informing the selection of clusters for targeted contrast enhancement.

This integrated approach—merging deep learning-based feature extraction, PCA, and hierarchical clustering—presents a robust strategy for automatically enhancing the contrast of similar regions within 4D-STEM data. By doing so, it significantly advances the automation of contrast enhancement, ensuring more efficient, accurate, and objective analysis of material structures. This methodology helps to streamline the process of identifying and enhancing similar regions within complex materials.[4]

Fig. 1. (left) Virtual BF STEM image, inset (upper left) indicates an example scattering and with the virtual mask overlay. (center) Virtual STEM image collected with an optimized annular mask. (right) Line profile from virtual images with the relative contrast level calculated from normalized intensities, with an An contrast increase from 28% to 39% is observed between images reconstructed from virtual BF and with an optimized annular mask.

Scanning Transmission Election Microscopy Observations of Twisted Epitaxial Molybdenum Disulfide-Gold-Molybdenum Disulfide Heterostructures

Yi Cui[1], Prof. Robert Sinclair[1]
[1]Department of Materials Science and Engineering, Stanford University, Stanford, United States

PS-01 (1), Lecture Theater 3, august 28, 2024, 10:30 - 12:30

Background incl. aims: Confinement of atoms and molecules inside the vdW gap of 2D materials provides a possible strategy for the synthesis of nanostructures that do not evolve 2D phases by themselves. In addition, precise orientation control of the guest 2D nanostructures in this heterogeneous system could provide a promising opportunity to engineer the tunable physical and chemical properties of this heterostructure. We have found a "twisted epitaxial" growth method to synthesize nanometer thick gold (Au) nanodiscs with an average diameter of 50 nm by encapsulating Au nanoparticles within twisted bilayer MoS2 then annealing.1,2 In this "twisted epitaxy" regime, both top and bottom substrates could interact with the grown Au epilayer and influence its crystallographic registry. Transmission electron microscopy (TEM) shows that, Au aligns midway within the twisted bilayer MoS2 when the twist angle is small. For larger bilayer twist angles, Au exhibits only a small misorientation with the bottom MoS2 which varies approximately sinusoidally with the twist angle of the bilayer MoS2. The discovery of twisted epitaxy therefore provides opportunities for tri-lattice heterostructure Moiré engineering and for structure-property investigation of 2D materials with advanced scanning transmission electron microscopy (STEM). Here, we present the STEM-annular bright field (ABF) imaging of so-called "Moiré of Moiré" in twisted epitaxial MoS2-Au-MoS2 trilayer heterostructures. Multislice ptychographic reconstruction shows the atomic structure of each layer and the Moiré pattern from each interface. We have also analyzed the Au plasmon energies and MoS2 excitons by electron energy loss spectroscopy (EELS) to establish whether any new electronic or optical properties might be generated by the twisted epitaxy.
Methods: In the present abstract, the STEM-ABF analysis was carried out on a Thermo Fisher double-corrected, Spectra TEM-STEM operating at 300 kV with a convergence semiangle of 30 mrads and a collection semiangle from 5 to 25 mrads. Multislice ptychography was performed under the same condition using an electron microscope pixelated array detector (EMPAD). Monochromated EELS measurements were conducted at 60 kV with a 60 meV energy resolution.
Results: In the twisted epitaxial MoS2-Au-MoS2 trilayer sample, the twist angle of bilayer MoS2 was determined to be 6.0o by selected area electron diffraction (SAED), and the orientation of the {220} planes of Au nanodisc was measured to have a 3.0o mismatch with the {110} planes of both MoS2 substrates. Therefore, there exists three primary Moirés in this trilayer heterostructure: Moiré from bilayer MoS2 {100} planes with a spacing of 2.7 nm, Moiré from Au {220} with bottom MoS2 {110} with a spacing of 1.4 nm, and Moiré from Au with top MoS2 {110} with a spacing of 1.4 nm. The three primary Moirés are difficult to image at the same time using conventional TEM imaging as it provides the averaged information of the heterostructure along the beam direction. Instead, the STEM-ABF image shows a larger period Moiré (~ 15 nm in spacing), which is attributed to Moiré of the two Moirés from Au with the top and bottom MoS2, respectively, due to their slightly different misorientation. Multislice ptychography iteratively solves for both the electron probe and the object in three dimensions (3D), sliced layer by layer, thus enabling detailed atomic structure visualization at varying depths of view within each slice.3 Employing multislice ptychography, the Moiré patterns of

the two MoS2-Au interfaces were resolved with atomic precision. In addition, the EEL spectrum from a typical twisted epitaxial Au nanodisc (in an approxiamtely rectangle shape with a length of 55 nm, a width of 35 nm, and a height of 3 nm determined by atomic force microscopy) encapsulated in bilayer MoS2 shows a long axis dipolar plasmon peak at 0.8 eV, a short axis dipolar plasmon at 1.0 eV, and a peak at 1.5 eV at the center of the nandisc. This result is different from that of previously reported epitaxial Au island on MoS2, where it shows a long axis dipolar plasmon ~ 1.3 eV and a short axis dipolar plasmon ~ 1.6 eV, indicating a different electronic and optical property of twisted epitaxial Au.4
Conclusion: Our investigation using a double-corrected and monochromated STEM combining ABF, multislice ptychography and EELS has allowed us to delve into the intricate Moiré structure and plasmon resonance of a twisted epitaxial MoS2-Au-MoS2 heterostructure. However, this exploration marks just the starting point, as more questions remain unanswered. For instance, whether there are lattice reconstructions at the twisted Au-MoS2 interface, how the Moiré of Moiré affects the electronic and optical properties of Au, etc. This paper will discuss progress along these lines and outline potential directions for future avenues of research.

Poster Group 2

Nanoscale materials characterization often uses highly energetic probes which can rapidly damage beam-sensitive materials, such as hybrid organic–inorganic compounds. Reducing the probe dose minimizes the damage, but often at the cost of lower signal-to-noise ratio (SNR) in the acquired data. This work reports the optimization and validation of principal component analysis (PCA) and nonnegative matrix factorization for the postprocessing of low-dose nanoscale characterization data. PCA is found to be the best approach for data denoising. However, the popular scree plot-based method for separation of principal and noise components results in inaccurate or excessively noisy models of the heterogeneous original data, even after Poissonian noise weighting. Manual separation of principal and noise components produces a denoised model which more accurately reproduces physical features present in the raw data while improving SNR by an order of magnitude. However, manual selection is time-consuming and potentially subjective. To suppress these disadvantages, a deep learning-based component classification method is proposed. The neural network model can examine PCA components and automatically classify them with an accuracy of >99% and ~1s for 100 components. Together, multivariate analysis and deep learning enable a deeper analysis of nanoscale materials' characterization, allowing as much information as possible to be extracted.

Investigating All-Inorganic Halide Perovskite Phase Transformations via in-situ 4D STEM Heating Experiments

Mr Tom Warwick[1], Mr. Paul Smeets[2,3], Mr. Roberto dos Reis[2,3]
[1]Gatan, Inc., Pleasanton, United States, [2]Department of Materials Science and Engineering, Northwestern University, Evanston, United States, [3]Northwestern University Atomic and Nanoscale Characterization Experimental (NUANCE) Center, Northwestern University, Evanston, United States

PS-03 (1), Lecture Theater 2, august 29, 2024, 14:00 - 16:00

Background incl. aims
Halide perovskite materials, in particular Cesium lead-based halides (CsPbX3, where X = Br or Cl), are known in the halide perovskite family due to their promising optoelectronic properties. Understanding any phase transitions in CsPbX3 that would occur under typical device operating conditions is crucial for assessing device thermal stability and structural integrity [1, 2]. This work focuses on elucidating phase transitions in CsPbX3 that occur as a result of thermal variations by utilizing in-situ four-dimensional scanning transmission electron microscopy (4D STEM). This approach captures their structural evolution across a temperature range from sub-ambient to the melting point.
Methods
Energy-filtered 4D STEM data were acquired using a JEOL ARM300F microscope outfitted with a GIF Continuum® and post-GIF K3® detector from Gatan. DigitalMicrograph® version 3.6 and eaSI™ technology were used for in-situ 4D STEM data acquisition. Digital Temperature modulation of the samples was achieved using a DENSsolutions heating holder controlled within DigitalMicrograph and a Gatan LN2 holder for cooling.
Results
The phase diagram of CsPbBr3 predicts multiple phase transformations as the material is heated from room temperature until its melting point at 500°C. The material begins in an orthorhombic (Pnma) phase and begins a phase transformation to a tetragonal (Cmcm) phase at 88°C, followed by a 2nd transformation to a cubic (P4/mbm) phase at 130°C that persists until the melting point. CsPbBr3 was heated from room temperature until its melting point and initial in-situ 4D STEM data shows temperature-dependent variation in the averaged diffraction patterns, seen in Figure 1. Furthermore, virtual bright field images derived from the in-situ 4D STEM data show dynamic reaction interfaces and evolving contrast during heating. These results emphasize the presence of structural evolution of CsPbBr3 about 60°C, 130°C, and above 500°C.
Conclusion
In-situ 4D STEM data acquisition of CsPbX3 during heating is a powerful methodology for quantitative analysis of the phase evolution of halide perovskites from ambient temperature until their melting point. The data collection tools available with in DigitalMicrograph link 4D STEM data with the experimental temperature profile from the heating holder, providing a detailed chronology of the phase evolution. This allows for a more concrete understanding of the stability ranges of the observed intermediate phases during heating and deeper insight into the material behavior under simulated operational temperatures. Adding complementary techniques such as in-situ electron energy loss spectroscopy (EELS) should provide important chemical information to further assess the structural behavior of CsPbX3 and its consequences on optoelectronic properties.

Depth sensitivity of atomic resolution secondary electron imaging

Professor Koh Saitoh[1], Hirokazu Tamaki[1]
[1]Institute of Materials and Systems for Sustainability, Nagoya University, Nagoya, Japan, [2]Department of Applied Physics, Nagoya University, Nagoya, Japan, [3]Hitachi High-Tech Corporation, Hitachinaka, Japan

Poster Group 2

Background incl. aims
Recent advances in spherical aberration-corrected electron microscopes have enabled us to observe not only the projected structure of a sample using transmission electrons but also the surface structure with atomic resolution using secondary electrons (SE) emitted from the sample [1,2,3]. Atom-resolved SE imaging of surface structures is one of the key challenginges. The first attempt was made by Ciston et al. for 2 x 6 reconstruction on the surface of SrTiO3 (001) [4]. This report showed that SE signal has a potential capability to detect surface structures uniquely formed only on the topmost surface of the material with a high spatial resolution. In this study, the depth resolution of the SE imaging is investigated using twisted layers of MoS2, which are the thinnest system composed of a surface layer and substrate. The spatial resolution and elemental contrast of the SE images are also evaluated.
Methods
Monolayer MoS2 was grown on SiO2 thin film formed on a silicon substrate by chemical vapor deposition (CVD). The monolayers were peeled off from the substrate and transferred to a carbon support film for TEM observation. Some of the MoS2 monolayers were stacked on the other monolayer MoS2 by rotating 30 deg. to fabricate twisted bilayer MoS2. An aberration-corrected scanning transmission electron microscope equipped with a cold field emission gun and Everhart-Thornley SE detector (Hitachi High-Tech HF-5000) was used to acquire atom-resolved SE and ADF-STEM images at an acceleration voltage of 200 kV. The convergence semi-angle of the incident beam was set to 23 mrad, and the acceptance angle of the ADF detector was set to 40-200 mrad.
Results
Figures 1(a) and 1(b) show ADF-STEM and SE images simultaneously taken from a region containing both monolayer (upper left) and bilayer (lower right) MoS2, respectively. The ADF-STEM image of the monolayer region shows Mo and S sites as bright spots with different intensity, or Z-squared contrast, confirming the projected structure of MoS2 [0001] incidence shown in Fig. 1(c). The SE image of the monolayer region is noisier than the ADF-STEM image, but shows signals at positions corresponding to the locations of Mo and S atoms, forming the six-membered rings of the MoS2 structure. Mo and S show a similar intensity, indicating that the observed signal is not due to the backscattered electrons but due to SEs emitted from the illuminated atoms and their surrounding regions. The spatial resolution of the ADF-STEM and SE images, which are estimated by the outermost peaks in the FFT patterns, are 0.1 nm, and 0.16 nm, respectively.
The ADF-STEM image of the bilayer region shows wheel-shaped atom clusters with 12-fold symmetry as indicated by the white circle in Fig. 1(a). The 12-fold wheel-shaped clusters are formed by stacking two MoS2 monolayers rotated by 30 deg. to each other. Figure 1(d) shows an atomic arrangement of the projection structure of the wheel-shaped cluster. The central bright dot of the wheel-shaped cluster corresponds to the superposed two Mo atoms and surrounding 12 dots correspond to 12 Mo atoms in the surface and second layers, 6 Mo atoms are in the surface layer and the other 6 Mo atoms are in the second layer. SE images of the bilayer region do not show the projection structure of

bilayer MoS2 but show the six-membered rings as observed in the SE image of the monolayer region. In other words, SE images selectively visualize only the surface monolayer. This result indicates that atomic-resolution SE imaging has an extremely high surface sensitivity and is very effective for the determination of the surface structure.
The SE image of the bilayer region is about 1.5 times brighter than the monolayer region. An FFT pattern of the SE image of the bilayer region shows 12 spots around the central spot, which are composed of 6 intense spots alternate with 6 weak spots. The FFT pattern can be understood as an overlap of two 6-fold patterns rotated by 30 degrees with different intensities. This confirms the fact that the SE image visualizes one of the monolayers more intensely than the other. The reason why the second layer is not visualized in SE imaging is considered to be because SEs emitted from the second layer and directed toward the detector are significantly attenuated as they pass through the surface layer.
Conclusion
In the present study, we found that high-resolution SE imaging selectively shows atomic arrangement of a surface monolayer, even though the monolayer is located on other materials. The present results indicate that high-resolution SE imaging has a high surface sensitivity of a monolayer level. We also confirmed that the transverse spatial resolution of the SE images does not differ significantly between the monolayer and bilayer MoS2, achieving at less than 0.2 nm. The thickness dependence of the SE yield should also be examined to clarify whether the SE production by energy transfer of excited states produced by primary electrons leads to the enhancement of the SE production beyond volume effects. A further study will be conducted on the formation mechanism of layer-number-contrast in SE imaging of atom layer materials.

Background incl. aims
Multi-twinned structures have been observed in technologically important crystal systems, for example diamond cubic and face-centered cubic (FCC) lattices, that include materials such as diamond, silicon, a wide range of noble metals, and their nanoscale counterparts. Beyond atomic building blocks, the special arrangements also occur in the self-assembly of nanoparticles (NP) and µm-sized colloidal particles and occupy parts of their phase diagrams. Spanning a wide range of length scales, the universality of the structures arises when the systems attempt to achieve multi-twinned structures by overcoming geometric misfits during minimizing surface energies with entirely {111} or close-packing facets. While it is fundamental to understand how strain is sustained upon twinned structures and symmetry breaking, the knowledge will be paramount in practical aspects such as guiding and controlling the thin film growth, anisotropic NP growth, and self-assembly of NPs. Au decahedral (Dh) NP, as the most prevalent multi-twinned model system, fits five tetrahedral motifs into a circle by sharing an axis resulting in a geometric misfit angle of 7.35°, or a disclination with power of -7.35°. Postulating how Au FCC lattice adopts the misfit, theoretical models have been developed to address the underlying lattice symmetry and inhomogeneous strain distribution separately. Yet, experimental reports regarding the former have been limited due to the relatively large X-ray beam sizes that do not fit the sizes of NPs. On the other hand, though the latter has been widely adapted in the thermodynamics of small (<10 nm) multi-twinned nanoparticles, previous literature has shown that, at edge length of 17 nm, the theory's is invalidated by shear strain that is observed in a defect-free Au Dh NP by high-resolution transmission electron microscopy (HR-TEM) imaging. Though the advancement of aberration-corrected scanning transmission electron microscopy (AC-STEM) imaging and ab initio calculation techniques brings new opportunities, along with challenges in complicated image analysis and limitation in particle size (usually below 10 nm), the gap between nanoscale and mesoscale has never been extended to gain insight from atomic system with straightforward interaction potentials.
Methods
In this work, we performed strain mapping using four-dimensional STEM (4D-STEM) on Au Dh NPs with edge lengths between 18 and 50 nm at single particle level. In 4D-STEM, a nm-sized electron probe (at a convergent angle of 0.6 mrad) offers nm spatial resolution and decouples the complex diffraction patterns (DP) of the entire five-fold twinned structure into single-crystalline patterns corresponding to each tetrahedral grain. As such, NP's lattice plane directions can be easily identified and aligned with strain components. Diffraction disks were tracked by circular Hough transformation for sub-pixel accuracy. DPs are acquired on an Electron Microscope Pixel Array Detector (EMPAD) to reduce step size and acquisition time. Further integration of AC-STEM is utilized to confirm the absence of large-scale defects, such as additional twin boundaries and disclination, in the NPs and to focus on the geometric effects, excluding other known pathways of strain relaxation.
Results

The resulted strain mappings across various particle sizes exhibit values and distributions agree with previous Dh models: ~ 2% of tensile strain along {220} direction concentrated at particle edges. From reciprocal space, we also observed ~ ±0.5% of shear strain on two sides of twin boundaries. Other results, such as strain along {002} direction, also match with finite element analysis (FEA) simulation based on the closing of geometric misfit. Additionally, since the crystallography of local lattice is being tacked across a particle, it is possible to map out local symmetries of Dh NP at nm spatial resolution for the first time. We have uncovered the particles we analyzed are mostly in body-centered tetragonal symmetry, yet as particle size increases, lattices near twin boundaries shift towards FCC symmetry. Furthermore, with the help of the small step size only made possible with EMPAD, our mappings show structural heterogeneity among tetrahedral grains and among particles we surveyed. The detailed features lead us to study how imperfect Dh geometry, such as particle edges, tip truncations, etc., contributes to variations in strain values and distributions. With FEA simulation, we associate the heterogeneity with the shifting of disclination away from the center of a particle because of statistical fluctuation of energetics during the fast growth of multi-twinned particles.

Conclusion

Using 4D-STEM strain mapping with an advanced pixelated detector at high frame rate, we have unveiled new information of Au Dh NP at particle sizes that were experimentally inaccessible before. The diffraction-based technique provides richness in the crystallographic information of nanostructure at high spatial resolution as well as approaches to in-depth data analysis beyond atomic imaging. The results help experimentally bridge a variety of previous theoretical concepts, including lattice symmetry, disclination shifting, and heterogeneity associated with particle growth energetics. The understanding of imbalanced geometry has future implication of precise control over anisotropic NP shapes and additional over-growth or etching. Fundamentally, the extension of length scale shows novel insights into mechanisms that nature choses to accommodate the geometric misfit by simple atomic potentials. We believe it will inspire assemblies at different length scales that leverage complex interactions.

Investigating multiferroic phase change dynamics using in-situ electron counted spectrum imaging with synchronized holder control

Liam Spillane[1], Dr Michele Conroy[2]
[1]Gatan Inc., Pleasanton, USA, [2]Department of Materials, London Centre of Nanotechnology, Henry Royce Institute, Imperial College London, London, UK

Poster Group 1

Improper ferroelectrics have strong potential for use in low power domain wall nano-electronic devices, as the formation and motion of conducting domain walls in such materials is governed by strain as opposed to their electric polarization [1,2]. Multimodal STEM spectrum imaging performed in the (scanning) transmission electron microscope (S)TEM is ideal for characterization of the ferroelectric domain dynamics in improper ferroelectrics, as the technique enables correlation of local chemistry and bonding information, with crystallographic and strain information determined from identical specimen regions at micro to (near) atomic scale.

The ferroic phase changes of the improper ferroelectric: Co-Cl, Cu-Cl and Fe-I based boracites ($M_3B_7O_{13}X$) are complex, with the materials undergoing multiple phase transitions from low temperature up to Tc. For example, Co-Cl boracite undergoes a trigonal to monoclinic transition at 296 K, monoclinic to orthorhombic transition at 500 K and orthorhombic to cubic transition at 673 K. No memory effect is apparent through the paraelectric to ferroelectric transition though memory effect from trigonal to monoclinic phases are observed [3].

MEMS based heating-biassing and cooling-biassing holders can be used to investigate phase change dynamics in these materials as a function of applied temperature and bias, though manual holder control becomes impractical if high stimuli resolution is required, due to the large number of temperature steps required for meaningful analysis in combination with the large number of individual biassing steps required at each temperature.

Here we present a holder automation strategy that takes advantage of the high-level communication Python library, ZMQ, to generalize external stimulus control within the DigitalMicrograph Python scripting framework. Control commands from the embedded in-situ SI data acquisition routine are sent via a generalized modular framework, enabling synchronized control of any external device supporting Python and ZMQ.

In-situ spectrum imaging was performed on Co-Cl, Cu-Cl and Fe-I based boracites ($M_3B_7O_{13}X$) with a 50-80 pA probe at 300 kV, using a counted mode EELS / energy filter system (GIF Continuum K3, Gatan) and flexible scan control system (Digiscan3). Domain wall dynamics were investigated as a function of applied bias at variable temperature using MEMS based in-situ heating-biassing, and cryogenic cooling-biassing holders (Lightning & Lightning-Arctic, DENSSolutions). Holder control and synchronization to data capture was performed using Python scripting in the DigitalMicrograph and DENSSolutions Impulse software packages. This scripting allowed multiple pass in-situ spectrum image (SI) data acquisition with all SI passes acquired at fixed holder stimuli conditions. Full voltage sweeps were applied at each temperature step in a temperature series. All data acquisition and holder control was fully automated . Data processing was performed using a combination of DigitalMicrograph (EELS, 4D STEM) and the Py4DSTEM (4D STEM) software packages.

Gatan's eaSI platform and DigitalMicrograph 3.60, allowed multipass single electron counted SI data capture with zero dead time between passes, at SI pixel rates of up to 3000 pix/s with continuous drift tracking in real time. A software screenshot showing the results of an in-situ energy-filtered 4D STEM data acquisition from Co-Cl boracite is shown in figure 1. Heating was applied in 10 ^{o}C steps from 270 ^{o}C – 340 ^{o}C. Biassing was applied at each temperature step in increments of 1 V from 0 V to Vmax = + 3.0 V and Vmin = -3.0 V and back to 0 V. The in-situ dataset comprises three primary data objects. An ADF image time series, a simultaneously acquired energy-filtered (EF) 4D STEM time series, and a holder auxiliary data plot. Measured temperature is shown in the auxiliary plot in pink. Voltage (holder bias) is shown in red. Both profiles are stepped, indicating SI passes are acquired at fixed holder stimuli conditions. A summed EF-CBED image from the highlighted region is also shown. In spite of the low probe current, the SNR of this image is high due to the high sensitivity of the counting detector. Two HOLZ rings are clearly visible.

Python scripting was successfully utilized to customize in-situ spectrum image capture, allowing synchronized control of a remote application using the ZMQ Python library. and a client-server design pattern. This design strategy was found to be a powerful means of leveraging the strengths of the native software application such as zero dead time multipass scanning, sub-pixel scanning, continuous drift tracking, etc. while also enabling holder control options not yet natively supported. In the case of Co-Cl, Cu-Cl and Fe-I based boracites ($M_3B_7O_{13}X$), this allows the setup of complex heating and biassing conditions at high temperature and bias resolution that would be unachievable if a manual approach was adopted. Such setups allow exploration of the FE memory affect at specific phase transitions in addition to complex analyses such as the correlation of strain mapping with local chemical and coordination environment changes at micro and macro domain walls in these materials.

Maximizing Speed and Sensitivity: Simultaneous High-throughput EDS-WDS Elemental Mapping in the SEM

Shangshang Mu[1], David Stowe[1]
[1]Gatan/EDAX, Pleasanton , United States

Poster Group 1

Background incl. aims
High-throughput Scanning Electron Microscopy-Energy Dispersive X-ray Spectroscopy (SEM-EDS) elemental mapping ensures the acquisition of multiple elemental maps simultaneously (hyperspectral mapping) within minimal timeframes. This process requires a high beam current on the SEM side to generate high input of X-ray counts, coupled with fast electronics of the Silicon Drift Detector (SDD) to operate at short pulse processing times, thereby efficiently converting incoming X-rays into output X-ray counts. However, shorter pulse processing times may lead to a low energy cut-off, as the noise level becomes comparable to that of the signal from low energy X-rays, presenting a challenge for high-throughput EDS mapping of light elements. While Wavelength Dispersive X-ray Spectroscopy (WDS) exhibits lower throughput than EDS at equivalent beam currents, its superior sensitivity and higher peak-to-background ratio enable better detection of light elements that may be difficult to observe using EDS alone. Therefore, simultaneous WDS mapping of light elements and high-throughput EDS mapping of higher-Z elements can facilitate rapid and accurate determination of element distribution for both light and higher-Z elements.
Methods
To demonstrate this capability, a boron steel sample was mapped using an EDAX Octane Elite Super EDS detector and an EDAX Lambda Plus WDS detector (Gatan inc.) in a Field Emission SEM. The beam current was set at 75 nA to achieve approximately 250,000 counts per second (cps) on the EDS detector. Capitalizing on advancements in SDD efficiency [1], a pulse processing time of 0.48 µs was used, resulting in an output of approximately 190,000 cps. An 80 Å diffracting crystal combined with polycapillary optics in the WDS detector were utilized to map B K. The region of interest was simultaneously mapped using EDS and WDS for a duration of 2 hours in the EDAX APEX 3.0 software (Gatan inc.). Drift corrections by the software were applied to compensate for sample drift induced by the high beam current.
Results
The SEM image (Figure 1a) unveils grains clusters segregated by relatively large melt-like pockets ranging from 5 to 25 µm in size. Orientation contrast highlights individual grains approximately 5-10 µm in size, with melt-like features as small as 1 µm developed at triple junctions. The resulting elemental maps are 512x400 pixels. The Co K EDS map (Figure 1b) illustrates a higher Co concentration within the grains in comparison to the melt-like pockets, while the Fe distribution depicted by EDS (Figure 1c) displays an inverse correlation with Co levels. Leveraging the superior sensitivity and high peak-to-background ratio of WDS, the WDS map of B K (Figure 1d) distinctly reveals a significantly higher concentration within the melt-like pockets and a depletion within the grains. However, due to the superfast pulse processing time utilized, the EDS map of B K (Figure 1e) fails to show the pronounced concentration contrast between melt-like pockets and grains.
Conclusion
In summary, simultaneous EDS-WDS mapping at a high beam current successfully delineated the element distribution for both the light element boron and the transition metals in a boron steel sample. By harnessing the benefits of both techniques, simultaneous high-throughput EDS-WDS

mapping enables the acquisition of high-quality X-ray map data within the shortest possible timeframe.

IM-06 (3), Lecture Theater 1, august 30, 2024, 14:00 - 16:00

Zeolite is a common porous material with a unique framework structure and periodically aligned nanosized pores. Zeolites have a wide range of industrial applications such as gas separation, catalysis, and ion exchange. In these applications, the material properties emerge from the interaction between the host zeolitic framework and guest materials, such as molecules or ions. However, zeolites are very weak to electron irradiation, and it is difficult to analyze this interaction at the atomic scale using electron microscopy.
Recently, we developed an optimum bright-field scanning transmission electron microscopy (OBF STEM) technique for low-dose observations [1]. OBF STEM uses a segmented-type STEM detector and can achieve a dose efficiency that is two orders of magnitude higher than that of annular bright field (ABF) STEM, a conventional phase-contrast-based STEM technique. Furthermore, the OBF STEM images can be acquired in real-time in sync with the probe scanning, which makes low-dose data collection much easier. It was shown that low-dose OBF STEM can visualize the atomic structure of zeolitic frameworks for both T (=Si or Al) and O sites, even in lattice defects such as twin interfaces. Furthermore, the Na-captured LTA-type sample, which is one of the most beam-sensitive zeolites, was observed using OBF STEM, which visualizes extra-framework Na sites with a lower occupancy of approximately 1/4 [2].
We then applied the low-dose OBF technique to the Cs-exchanged LTA-type zeolites. Cs exchange is a very important application for the removal of hazardous chemicals, and understanding how Cs species are captured inside this material is of great importance. The atomic structures of the Na- and Cs-captured LTA samples were investigated using high resolution TEM (HRTEM) in the literature [3]. However, because of the higher Al content inside the LTA framework (Si/Al=1), which decreases the electron illumination resistance, the attainable spatial resolution remains limited. In this study, we observed Cs-LTA zeolites using the OBF STEM technique with high spatial resolution (~1 Å) under low-dose conditions, with the aim of revealing the interactions between host zeolitic frameworks and captured guest cations.
We prepared Cs-exchanged LTA-type zeolite samples using the ion-exchange procedure of a commercially available Na-captured LTA zeolite sample with a CsCl aqueous solution. The Cs-LTA sample was gently crushed using an agate mortar and then dispersed onto a TEM grid with a carbon support film. We then observed the Cs-LTA sample using the OBF STEM technique with aberration-corrected STEM equipped with a segmented detector. To suppress the irradiation damage, the probe current was set to 0.16 pA, which is more than two orders of magnitude lower than the usual STEM observation conditions.
Figure 1(a) shows the OBF STEM image of the Na-LTA zeolite sample. The LTA-type has a cubic shape framework, and eight-membered rings (8MRs) can be observed along the [100] zone-axis. In Na-LTA-type zeolites, the Na cations captured inside the 8MRs split into four sites, with an occupancy of approximately 1/4 [4]. In addition to the clear visualization of the T and O atomic sites inside the LTA

framework, the OBF image shows a slight contrast around the center of 8MR, corresponding to the captured Na cations [2]. We then observed the Cs-captured sample from the [100] zone-axis using OBF STEM, as shown in Figure 1(b). The OBF image contrast at the center of the 8MRs changed into a distinct sharp one compared with the Na-LTA case, indicating that the captured Cs cations were rigidly confined into the LTA framework instead of splitting into multiple sites with low occupancy. This observation agrees well with the literature using HRTEM and density functional theory (DFT) calculations [3], showing the capabilities of OBF STEM to directly observe captured cation sites inside zeolites at the atomic scale.

We applied a low-dose OBF STEM technique to the Cs-exchanged LTA-type zeolite samples. The atomic structure was clearly visualized for not only the LTA framework structures but also the captured Cs sites, identifying the different behavior of the captured cations in comparison to the Na-LTA case. This result shows that the OBF STEM technique is promising for the atomic-scale analysis of zeolites, including extra-framework cations.

Full-field illumination ptychography with a structured electron beam

Hirokazu Tamaki[1,2], Dr. Koh Saitoh[3]
[1]Graduate School of Engineering, Nagoya University, Nagoya, Japan, [2]Research & Development group, Hitachi Ltd., Kokubunji, Japan, [3]Institute of Materials and Systems for Sustainability, Nagoya University, Nagoya, Japan

IM-03 (2), Plenary, august 28, 2024, 14:00 - 16:00

Background incl. aims
Coherent diffractive imaging (CDI) is a technique for reconstructing the complex wavefield from far-field diffraction pattern. CDI has advanced rapidly with the improvement of recent detectors and computing performances, and among them, ptychography has been attracting great interest. One of the key challenges in ptychography is accurate phase reconstruction for large structures. The diffraction intensity carrying the information of large structures is generally concentrated in the low scattering angle region and is often saturated beyond the dynamic range of the detectors. To overcome this obstacle, near-field ptychogrpahy [1][2], which utilizes the Fresnel diffraction pattern for the reconstruction, has been proposed in recent years. In this study, we propose a novel configuration for near-field ptychography with full-field illumination using a structured electron beam, aiming at the accurate and efficient observation of large structures.

Methods
The proposed method is configured on the conventional TEM setups. A series of in-line holograms observed in the Fresnel region below the specimen are obtained at different beam positions by scanning the illumination beam. Then, both the wavefield of the illumination beam and the complex transmission function of the specimen are reconstructed from the obtained holograms through a ptychographic procedure. This method does not require a spatial restriction on the specimen plane as a constraint, and instead introduces an irregular structure into the illumination beam that works as an alternative constraint. The structured beam is generated by using a film with random openings, placed in the condenser lens system above the specimen. The diameter of the incident beam is adjusted so that the entire field of view is always illuminated during the scanning. Full-field illumination prevents error accumulation when reconstructing a large field of view compared with conventional ptychographic reconstruction, which “concatenates” small patches of local structures. Full-field illumination provides uniform redundancy over the field of view since the entire field of view of each hologram is fully overlapped. These contribute to accurate and robust reconstruction of large structures. The use of random openings for beam structuring also suppresses coherence degradation of the illumination beam due to inelastic scattering, thereby improving the accuracy of phase determination.
The performance of the proposed method was first evaluated using simulated holograms. Then, its experimental feasibility was evaluated using MgO particles.

Results
Graphic 1a shows one of the in-line holograms obtained below the specimen. The wavefield of the illumination beam and transmission function of the specimen were reconstructed from the obtained holograms. The reconstructed amplitude (Graphic 1b) and phase (Graphic 1c) of the specimen transmission function show good agreement with the given structure. The phase reconstruction error

was 1/12,097 and 1/3,485 of the wavelength for the fine (20 nm) and large (400 nm) structures, respectively. Both are comparable to other accurate phase measurement methods [3].
Graphics 2a and 2b respectively show the amplitude and phase components of the transmission function reconstructed from the experimental holograms of MgO particles. The reconstructed phase component shows a periodic phase contour at the edge of the particle, and also shows a uniform phase in the constant thickness region of the particles with faces oriented toward the beam direction. These results are consistent with the particle shape, indicating the validity of the method.

Conclusion
In this study, we proposed a new configuration for near-field ptychography using full-field illumination with a structured electron beam. A simulation study demonstrated phase reconstruction with an accuracy of 1/3,485 of the wavelength, a performance comparable to other phase measurement methods. An experimental study using a MgO crystal also showed reasonable reconstruction consistent with the specimen structure. These results suggest that this method can be adopted for accurate and efficient observation of large structures.

LS-04 (1), Lecture Theater 4, august 29, 2024, 10:30 - 12:30

Structural colour is a phenomenon whereby colour results from underlying nanostructures. For example, green colouration in the butterflies Erora opisena and Parides sesostris is a result of light interference with photonic crystals, which arrange in a single Gyroid geometry. Formation of these complex geometries and evolution of the resulting optical signals is not fully understood.

We have developed an in vivo hyperspectral microscopy technique to detect and measure optical signals emitted from wing scales of living P. sesostris pupae as they develop. Our aim is to couple these in vivo hyperspectral data with ex situ high resolution electron microscopy (SEM/TEM) and 3-dimensional imaging (3-D FIB-SEM, TEM tomography) data in order to link photonic properties to underlying nanoscale geometries of developing gyroids, over time.

Optical signals resulting from the formation of Gyroid photonic crystals begin to be emitted from the wing scales of developing pupae approximately 13 days after pupation. At this stage, a small signal peaking at ~635 nm (red) can be observed and electron microscopy confirms the onset of gyroid formation within a cellular environment. Over the next few days, the emitted spectra then increase in reflectance and the peak shifts towards shorter wavelengths by approximately 10 nm. Electron microscopy of wing scales fixed 15 days after pupation show well defined gyroid nanostructures still within a cellular environment. On emergence at ~20 days after pupation, the adult butterfly wing scales are visibly green, with gyroid formation now complete and existent in a dry state.

Due to the complex nature and length scales of these developing gyroid structures, 3-D information at the nanoscale is required to better understand their formation and development. Both FIB-SEM and TEM tomography methods offer the potential to reveal 3-D information across the nano- and micron-length scales relevant to our geometric features of interest. Preliminary FIB-SEM data reveal that we can visualise gyroid structures within wing scales of developing pupae that have been prepared using heavy metal staining and resin embedding techniques. We explore the suitability of these methods to investigate gyroid geometries in developing wing scales at time points where key shifts in optical properties have been identified with hyperspectral imaging (e.g. 13-20 days after pupation).

This multi-modal approach allows us to move toward validating mathematical modelling of simulated changes in structural geometries and functional (photonic) properties against actual structural and spectral data from developing gyroids in butterfly wing scales, over time. Such knowledge will contribute to exciting developments in fields such as synthetic biology, biomimetics, and drug delivery applications.

Poster Group 1

Background:
In recent years, the adoption of three-dimensional (3D) multicellular models, such as organoids, spheroids, and organs-on-chips, has surged in biological research due to their superior physiological relevance compared to traditional cell culture methods. These models, cultivated from stem cells or organ progenitor cells, emulate the intricate structure and functionality of real organs, providing researchers with invaluable insights into organ development, disease mechanisms, and drug responses within a controlled laboratory environment. They offer a versatile platform derived from various tissues, including the brain, liver, kidney, intestine, and pancreas, holding immense promise for advancing biomedical research, personalized medicine, and drug discovery endeavours.
Understanding the complex structure of these 3D multicellular models poses a significant challenge, especially when aiming for high resolution. However, recent advancements in electron microscopy (EM) have introduced techniques enabling comprehensive imaging of these samples. Volume electron microscopy (vEM) has emerged as a powerful tool for analysing their overall structure and potential variations corresponding to different states, offering nanoscale resolution imaging capabilities.
While cells and tissues have been extensively studied in two-dimensional (2D) settings, successful machine learning and deep learning solutions for detection and classification have been developed. However, transitioning to 3D complex structures introduces novel complexities. Developing effective deep learning models is hindered by the limited human capacity to annotate large volumes of 3D data accurately and reliably. Additionally, the availability of 3D algorithms significantly lags behind those for 2D, creating an annotation bottleneck that hampers progress and stifles the development of innovative 3D solutions.

Methods :
This study focuses on cancer cell organoids (HCT116) under different conditions, imaged using a Serial Block Face (SBF) Katana microtome within a Scanning Electron Microscope (SEM). The SBF-SEM technique involves a miniature ultra-microtome attached to the motorized stage of an SEM, where a diamond knife repeatedly removes thin layers from a sample block. After each section is removed, the exposed block surface is imaged with a back-scattered electron detector. This automated in-situ method enables the acquisition of a series of images throughout the depth of a large sample. From this stack of 2D images, 3D morphology can be reconstructed, and various organelles of interest can be segmented using developed deep learning models.

Results:

Our study demonstrates the suitability of SBF-SEM for imaging organoids, allowing for the imaging of large volume samples at a relatively fast acquisition speed. The field of view is comparable to Array Tomography (up to 3 mm) but surpasses that of Focus Ion Beam-SEM (less than 100 µm). With this technology, we successfully imaged the entire organoid within a reasonable timeframe, with sufficient resolution to segment cells, cellular compartments, and organelles of the organoid. Furthermore, we are utilizing manual annotation and deep learning on the image dataset to identify structural changes in cells based on the conditions of the organoid and to correlate with 3D imaging with others technics, like confocal microscopy.

Conclusion :
However, the utility of these models necessitates tools for imaging and analysing the large quantity of complex 3D images required for comprehensive analysis. Convolutional neural networks trained on this extensive dataset can precisely detect and quantify subcellular and multicellular features, including mitotic and apoptotic events, multicellular structures like rosettes, cells, and organelles. The integration of high-resolution 3D microscopy techniques with machine learning approaches enables quantitative descriptions of organoid morphogenesis correlated with phenotypic characterization, facilitating the deciphering of mechanisms involved in morphogenesis and human physiopathology, as well as responses to extreme conditions.

Background incl. aims

Sn-Ag-Cu (SAC) alloys are commonly used in lead-free solder joints in electronic interconnection applications, where joint reliability can be limited by creep. Sn-3Ag-0.5Cu wt.% (SAC305) has become widespread solder joints in thermal cycling. Sn-1Ag-0.5Cu wt.% (SAC105) is often selected for its superior drop impact reliability. SAC solder alloys have more than 95% of the β-Sn phase in a microstructure consisting of β-Sn dendrites and eutectic regions after solidification with Cu6Sn5 and Ag3Sn embedded within the β-Sn matrix. These solders demonstrate creep susceptibility even at room temperature (298 K is T/T_M ~ 0.6) and intermetallic compounds (IMCs) within the solder matrix play an important role in reliability. This study aims to explore the role of the IMC content to address how strain accumulates and how the microstructure evolves with respect to IMC content. This investigation is expected to promote the development of a new understanding concerning the mechanisms of microstructural deformation of solder alloys.

Methods

The creep behaviour of bulk solder samples with different compositions, e.g. high-purity tin (99.99% Sn), SAC105 and SAC305 is investigated under constant stress at room temperature (~298 K). The deformation mechanisms are investigated using electron backscatter diffraction (EBSD) and strain heterogeneity is identified by two-dimensional digital image correlation (2D-DIC).

Results

At the macroscopic lengthscale, the IMC content controls the appearance of heterogenous deformation, the size and the extent of the neck. At the microscopic scale, the deformation initiates in the β-Sn phases around IMCs for the IMC-containing samples subject to low strain rates in the secondary stage creep, resulting in local recrystallisation. Large recrystallised grains form and propagate into the β-Sn matrix at higher creep strain in the tertiary stage creep. An obstacle-controlled and thermal-activated dislocation creep is the dominant mechanism for these solder samples with different IMC contents.

Conclusion

Both macroscopic and microscopic heterogeneous deformation have been observed for large-scale Sn-based samples during uniaxial creep at room temperature and constant stress. The creep performance of the samples shows dependence on the IMC content for HP Sn, SAC105 and SAC305 samples. SAC105 samples have been observed to have the best resistance to creep at constant stress

and room temperature, and it therefore would be sensible to optimise the IMC content subject to various load conditions.

Poster Group 2

The phenomenon of electron-beam-induced charging of specimens in the transmission electron microscope (TEM) is attracting increasing attention, both for fundamental reasons and because it has a strong influence on image contrast and quality, in particular when studying insulating and (cryo-)biological specimens [1], in which it is responsible for the bee-swarm or Berriman effect [2-4]. Electron-beam-induced charging is generally believed to result from secondary electron emission from specimen surfaces as a result of primary electron bombardment. However, the underlying physics is not yet fully understood.

Recent developments in off-axis electron holography in TEM offer the possibility to directly map charge density distributions in materials in real space [5, 6] as a function of parameters such as dose (rate), applied voltage and specimen temperature.

Figure 1 shows a measurement of electron-beam-induced charging of a needle-shaped specimen recorded at 300 kV using off-axis electron holography in the TEM at an electron dose rate of approximately 0.9 e-/Å2/s. The needle contains an apex of insulating dolomite (CaMg(CO3)2) and a W base. These two regions are separated from each other by Pt, which was deposited in a focused ion beam scanning electron microscope. The phase contour map shows that the needle is charged at its apex. The contours suggest the presence of a dipole-like charge distribution along the length of the needle. Asymmetry in the phase contour map results primarily from the influence of the perturbed reference wave. There is neither a dose-rate nor a total dose dependence of charging in this needle (not shown).

Surprisingly, a decrease in the reconstructed amplitude is visible in the vacuum region around the apex region. Although this observation is suggestive of a time-dependent charging and discharging process, no double exposure effects are visible in the recorded holograms in the form of Moiré fringes. Secondary electron emission alone may not be sufficient to interpret this result. Coincidence measurements between secondary electrons and electron energy-loss spectra may help to determine the physical origin of secondary electron emission in such samples. Parameters that include the distance to surrounding regions of the specimen and microscope, the presence of surface contamination, the specimen temperature, the presence of residual gas in the TEM column and the voltage applied to the specimen should be varied systematically in such experiments, in order to understand their influence on electron-beam-induced charging and to unravel the underlying physics of charging during illumination by high-energy electrons (and photons) [7].

OpenECCI - A Streamlined Open-Source Workflow for Electron Channelling Contrast Imaging of Crystal Defects

Zhou Xu[1], Dr. Håkon W. Ånes[2,3], Dr. Sergey Gorelick[1,4], Dr. Xiya Fang[1], Dr. Peter Miller[1]
[1]Monash Centre for Electron Microscopy, Clayton, Australia, [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway, [3]Xnovo Technology Aps, Køge, Denmark, [4]Ramaciotti Centre for Cryo-Electron Microscopy, Clayton , Australia
IM-06 (3), Lecture Theater 1, august 30, 2024, 14:00 - 16:00

Background
Quantitative analysis of crystal defects, such as dislocations, stacking faults, etc., has traditionally been exclusive to transmission electron microscopes (TEM) for decades [1]. This technique involves stereo-tilting of a crystal to the “two-beam” diffraction orientations with the assistance of transmission Kikuchi pattern projected on a phosphor screen or a camera. Recent years, Electron Channelling Contrast Imaging (ECCI) techniques, including accurate ECCI [2], controlled ECCI [3] and rotational ECCI [4], have gained increasing interest for quantitative defect analysis in bulk specimens. Unlike TEM, ECCI in SEM offers easier, less intrusive sample preparation, and fewer sample-prep induced artifacts. Additionally, ECCI enables examination of larger polished surfaces, yielding more statistically representative results. Nevertheless, several challenges hinder its widespread adoption:

- High spatial resolution accurate ECCI requires modified SEM column alignment for orientation control [2].
- Controlled ECCI requires proprietary software and additional hardware for precise orientation control [3, 5].
- There is a lack of reliable method for measuring and controlling the electron beam convergence angle inside SEM.
- Absence of a quantitative method for assessing sample stage tilt/rotation accuracy and repeatability for ECCI.
- For controlled ECCI, coordinating the identification of a feature between EBSD map and SEM image, and applying stereo-tilt without losing the feature of interest could be challenging.

Hence, our current work aims to address these issues by leveraging the open-source software community to develop a more accurate and user-friendly ECCI workflow.

Methods
In this study, we present a refined controlled ECCI workflow using electron channelling patterns with moderate spatial resolution for automated orientation calibration. Utilizing open-source packages such as EMsoft, Orix, and Kikuchipy, we developed an interactive Python package to streamline the ECCI workflow. This package accurately predicts the required sample stage tilt and rotation to achieve "two-beam" orientations based on Kikuchi pattern simulations. Additionally, SEM stage tilt/rotation accuracy and repeatability have been quantitatively assessed by comparing experimental electron channelling patterns with simulations. Furthermore, an automated routine for measuring the electron beam convergence angle has been tested based on OpenCV package. Lastly, we have developed a routine for correlating EBSD maps with SEM images (or specimen stage position) to facilitate stereo-tilt without losing the region of interest.

Results

Fig. 1 illustrates a brief summary of the workflow. Fig.1A shows a blended image of a EBSD map overlaid on the corresponding BSE backscattered electron image. The EBSD map is homographically transformed to correct the scan distortion induced by 70 deg stage tilt, so that all the feature positions on EBSD map and BSE image are well aligned. The interactive plot allows users to click on any point within the map to obtain SEM stage position and corresponding Euler angles from EBSD. The RKP reflected Kikuchi pattern from the point can also be simulated from the Euler angles, i.e. Fig. 1B, 1C. Fig. 1B is an overview Kikuchi pattern with relatively large angular range showing neighbouring poles and bands as a guiding map for stereo-tilt. Fig. 1C provides a zoomed-in region (blue box in Fig. 1B) for finding suitable "two-beam" orientations. By clicking on points within the pattern, users receive recommended stage rotation and tilt for orienting the point to the electron beam incident direction. Once a suitable orientation is achieved, ECC images can be acquired. For example, Fig. 1D and 1E depict ECC images acquired at 20kV, showing dislocations and stacking faults, respectively. Fig. 1D shows an array of dislocations piled up at a grain boundary. Most of the dislocations have dissociated into partial dislocations with Burgers vectors of ±1⁄2[10¯1]. Fig. 1E shows a few stacking faults on (1¯1 ¯1) close to a (11¯1) twin boundary. By analysing the beat pattern (oscillating intensity) across the stacking fault. The Effective extinction distance can be estimated ξ_g^eff = 13.7 nm. The total visibility depth of ECCI contrast at 20kV is approximately 80nm.

Conclusion

The OpenECCI package and the developed workflow offer a reliable and convenient method for ECCI experiments. Notable achievements include:

- With the stage accuracy and repeatability assessment routine, it has been demonstrated that many native SEM stages are accurate enough for ECCI without high precision substages.
- Providing reliable guidance on setting ECC imaging conditions through the measurement of electron beam convergence angle
- Streamlining the workflow for ECCI acquisition and data post-analysis through an interactive software interface that correlates EBSD maps, SEM images, and Kikuchi pattern simulations.
- OpenECCI is freely accessible to all researchers. Facilitated by its reliance on open-source packages, it could democratize the access to ECCI technique.

Background
The development of nanometer-scaled electronic devices with reduced dimensions, involving new materials or new architectures such as Magnetic Random Access Memories (MRAM), memristors or Phase Change Memories (PCM)1, requires a deeper understanding of their operating properties. While electrical and physical characterizations are widely used to monitor and evaluate both the device performance and the quality of the layer stack, there is a lack of knowledge on how the electromagnetic fields are precisely mediated along devices at the nanoscale level. Correlating electric fields mapped at the nanoscale across a chosen device with its structural properties and chemical composition would give new insights on the local electrical properties such as resistivity, polarisation, and charge traps.
Off-axis Electron Holography (EH) is an interferometric technique that allows quantitative mapping of electrical potentials inside and around the specimen, as well as the measurement of charge distributions2. However, operando EH has been rarely used, in particular on real devices3,4, because of key issues such as specimen preparation, surface damage layers, stray field and electron radiation. We will present the methodology that we have been developing for mapping the electrical properties of nano-electronic devices extracted directly from production lines without using a probe-based approach. Taking the example of phase change memory cell, we will show how electron holography can be used to measure in situ the resistivity distribution within the active layer after changing its state.

Methods
Phase-change materials exhibit a huge change of electrical resistivity between the amorphous (high resistance) and crystalline phase (low resistance). The electrical resistivity encodes the state of the bit, denoted SET for the crystalline state (low resistance) and RESET for the amorphous state (high resistance). To read the device, the resistance is measured by biasing the top and bottom electrode connected to a thin metallic filament called the “heater”. To write, a high-amplitude current pulse is injected, whose exact form depends on whether the operation is to stabilize the crystalline phase (SET) or the amorphous state (RESET). Current passing through the heater and GST layer causes localised Joule heating; the associated rise in temperature in turn causes the phase change. To SET, a relatively long pulse allows gradual crystallisation of the amorphous state whilst for RESET, a short pulse induces rapid melt-quench of the crystalline to amorphous state.
In situ biasing TEM experiments necessitate a specific and complex sample preparation that minimizes preparation artifacts whilst ensuring the electrical functionality of the nanodevice itself. The specimen-device was extracted from production lines before being thinned by focused ion-beam (FIB) and contacted to a chip with predefined electrical contacts, similarly to our previous work on electrostatic fields.5 An important part of the preparation was to preserve the encapsulation layer of insulating material all around the heater and GST layer. Special care was also taken to avoid any electrical discharges which would destroy the device. Holograms were recorded during long exposure

time using dynamical automation for compensating instabilities under bias, and while measuring the total current. Experimental phase images were then compared to additional numerical simulations using finite element modelling (FEM) including factors such as specimen geometry, stray fields and local resistivity.

Results

The GST layer within the device is initially crystalline (Initial state) and holograms were first recorded under a DC bias as if the memory was to be read. The layer was then switched to an amorphous state (Final state) by sending a sequence of pulses. Remarkably, the thin lamella survived the injection of peak currents of several hundreds of µA during the pulse. The overall resistance, measured under a biasing of 0.5 V during the holography experiments, changed radically between the initial and final states, increasing 5-fold after switching.
The corresponding phase images in initial and final states are presented in Figure b and e, respectively. We can clearly see the difference of the potential distribution between both states, with a dome-like shape in spanning the GST layer in the final state after amorphisation. The electrical information, in the form of isophase contours, has also been superimposed onto the conventional TEM images (Figure a and d) to help visualise the region involved. We can see, notably, that the phase contours seem to radiate outwards from the tip of the heater into the GST layer.
We obtained a very good agreement between experimental and simulated phase images using finite element modeling (Figure b and Figure e). This agreement gives access to the distribution of the electric potential within the device, and therefore to the local resistivity with the Ohm's law. From the reasonable assumption that the conductivity is radially symmetric around the heater tip and using the experimentally measured total current flowing through the device in situ, we determined the local map of the conductivity. A small seed of highly resistive material around the heater tip was revealed in the initial crystalline state and for the final state, the crystalline to amorphous transformation occurred at a certain radius, about 10 nm, from the heater tip.

Figure. Conventional bright-field TEM image, Initial state (a), Final state (d) with isophase contours (values on the right) extracted from experimental phase maps, Initial (b), Final (e). Simulated phase maps, Initial (c), Final (f). In dotted line the dome-like shape where the phase change occurs. Scale bars are 20 nm.

Conclusion
We developed a new methodology to map the local resistivity across the active area of an individual device in operation. This method, based on operando electron holography, has been applied on a PCM cell and directly highlights unexpected features. On switching the device by electrical pulses, we demonstrated that electrical resistance is inhomogeneous near the heater. This study shows the power of our methodology for studying the local electrical properties of active devices and can be applied in a general way.

PS-03 (2), Lecture Theater 2, august 30, 2024, 10:30 - 12:30

The emergence of fast pixelated direct electron detectors over the last years is allowing experiments in four-dimensional scanning transmission electron microscopy (4D-STEM) that would previously be too slow or noisy to be feasible, for example enabling the assessment of internal electric fields with high spatial resolution and precision[1–4] However, the electric field strength of long range built-in electric fields present in semiconductor devices, for example those associated with p-n junctions, is typically three orders of magnitude smaller than atomic electric fields, making 4D-STEM experiments in such systems challenging. It is therefore interesting to assess the detection limit and signal to noise that can be expected depending on the TEM operation conditions.

In this presentation, we describe how the quantification, sensitivity and spatial resolution of electric field mapping in a silicon p-n junction are influenced by the acquisition parameters in a momentum-resolved 4D-STEM experiment [3,5] comparing two different TEM setups differing in brand and in age by 10 years: the first setup, a TFS Titan Ultimate, was installed in 2012; the second, a Jeol Neo Arm in 2022. Both instruments provide 4D STEM capabilities using a Merlin camera based on medipix technology from Quantum Detectors. We have used the center-of-mass approach to analyze the diffraction patterns, obtained on a focused ion beam prepared silicon sample containing a p-n junction.

It will be shown that the success of the quantitative measurements depends not only on the correct estimation of the dead layer, but also on the acquisition conditions, most importantly the electron beam convergence angle.

The detection limit, defined as the three-sigma standard deviation of the field value away from the field containing region, was evaluated both as a function of beam semi-convergence angle as well as TEM setup. It was observed that the electric field precision improves by decreasing the semi-convergence angle [5]. For example, at a convergence angle of about 200 µrad, the detection limit was as good as 0.01 MV/cm, and it can even be lowered to 0.007 MV/cm in the more recent TEM setup. While such a low convergence angle setting gives the best detection limit and signal to noise ratio of the electric field (SNR 10 and 20, respectively), the increased probe size (estimated around 10 nm) can lead to an underestimation of the electric field value if the field containing region is of similar size as the electron probe. This was the case in the sample under study, where the field containing region was about 50 nm wide. Increasing the convergence angle to about 1 mrad avoids the underestimation of the field since the probe size is smaller (3-4 nm), at the expense of an increased detection limit. With about 1 mrad convergence angle a precision of 0.087 and 0.030 MV/cm with SNR 1.8 and 4.7 were achieved, respectively. As an example, maps of the modulus of the electric field are shown in Fig. 1 together with electric field profiles integrating either over 12 or 90 nm at three different convergence angles, where the Jeol Neo Arm is operated in Lorentz STEM mode.

The effect of electron dose is an important parameter, in particular in relation to beam sensitive materials. The influence of dose was evaluated and invariable electric field profiles were obtained using an electron dose as low as 24 e-/Å. Of course, the precision of the measurement does depend on dose. It was shown that for an average electron count of about 25 -75 counts per px, the detection limit does not further decrease for increased exposure times. Above this number of counts, the detection limit seems no longer limited by statistical Poisson noise on the detector, but by experimental instabilities, such as fluctuations on the high tension or lens currents or irregularities on the sample such as surface roughness.
In addition, in-situ electrical biasing coupled to momentum-resolved 4D-STEM measurements were performed, investigating the study of the degree of ideality of the junction abruptness, allowing the detection of phenomena like dopant segregation or interdiffusion [4].

This work paves the way for the development of advanced STEM based techniques able to provide imaging and quantification of built-in electric fields, potentials and charge densities in semiconductor devices with high spatial resolution, providing crucial feedback to improve growth/device fabrication processes.

Figure 1: 4D STEM maps at different convergence angle: The local modulus of the electric field is represented using three different Lorentz STEM modes of the Jeol Neo Arm, with three different convergence angles. Profiles are made along 12 nm, top row, and along 90 nm, bottom row.

Background
Among dielectric materials, HfO2 and Al2O3 are widely studied for micro and nanoelectronic applications. They present very interesting properties for several types of devices such as a higher dielectric constant compared to SiO2, high thermal stability and a compatibility with complementary metal oxide semiconductor (CMOS) technologies. For instance, resistive random-access memory (RRAM) devices [1, 2] or memristor devices [3] containing high-κ HfO2 and Al2O3 dielectrics are promising candidates in neuromorphic computing. However, the exact location of the charge stored in such devices is subject of debate and hence the mechanisms for charge trapping remain unclear. Particularly, the influence of interface charges has rarely been addressed because of the lack of suitable characterization techniques.
Whilst dielectric properties can be readily measured macroscopically using electrical methods, the task is difficult at the nanoscale. What is missing is a local and direct measurement of the electrical potential distribution within such devices upon biasing. Indeed, the phase of the electron hologram can be directly related to the electrostatic potential encountered by the fast electron along its trajectory. Recently, we were able to perform operando electron holography experiments in the same region under different biases and to successfully map the electric potential across a working SiO2-based MOS nanocapacitor with unprecedented sensitivity [4]. We observed an unexpected charging of the dielectric at both interfaces with the electrodes, over a distance extending up to few nanometers, a value much larger than the structural or chemical width of each interface [4]. In this study, we aim to take one step further to quantify the trapped charge at several interfaces, including insulator-insulator interfaces and metal-insulator interfaces, for which we have designed two thin tri-layer nanocapacitors: TiN/HfO2/Al2O3/HfO2/TiN (T-1) and TiN/Al2O3/HfO2/Al2O3/TiN (T-2) as shown in Fig. 1(a) & (b).

Methods
The tri-layer nanocapacitors were fabricated by atomic layer deposition (ALD). Each HfO2 or Al2O3 layer has a nominal thickness of 20 nm. TiN layers were deposited by sputtering before and after the insulating layer to serve as top and bottom electrodes during electrical biasing. In situ biasing TEM experiments necessitate a specific and complex sample preparation that minimizes preparation artifacts whilst ensuring the electrical functionality of the specimen itself. Specimens were prepared by FIB (FEI Helios 600i), on a Hummingbird chip-based biasing holder. Holography experiments were caried out using a Hitachi HF-3300 (I2TEM) microscope operating at 300 kV in Lorentz mode enabling a large field of view with a spatial resolution of 0.5 nm. Holograms were acquired during long exposure time using dynamical automation for compensating instabilities under different applied bias [5]. Finite element method (FEM) modelling was performed using COMSOL software to interpret

the phase profiles quantitatively, including factors such as specimen geometry, preparation artefacts and stray fields around the sample device.

Results

Figures (a) and (b) show the studied regions for T-1 and T-2, respectively while the corresponding phase maps extracted from holograms acquired under a bias of 6V are given in Figure (b) and (d), respectively. The phase map has been corrected by the reference hologram at 0 V, by which the experimental artifacts were removed and the remaining signal can be attributed to the applied electrical biasing. The artifacts comprise the possible variable lamella thickness, damage layers, diffraction contrast, and electron-beam-induced charging.
The amplitude of the measured phase profiles across the tri-layer insulators (Figures (e) and (f)) extracted from phase images rise with increased bias, and appear symmetric when switching the sign of the bias, for example, 6 V and -6 V. However, the potential distributions as well as the measured electrical fields are quite different from those expected theoretically. Considering a relative permittivity of 7.4 for Al2O3 and 18 for HfO2, both measured by C-V tests at 100 kHz for their macro devices, the electric field should be 2.44 times higher in Al2O3 than HfO2, which consequently should result in a 2.44 times higher potential drop in Al2O3. In contrast, the experimental phase profiles highlight a homogenous electric field in all the layers for both T-1 and T-2 due to the appearance of charged layers at insulator-insulator interfaces as well as metal-insulator interfaces. Combined with extensive FEM simulations, we successfully quantified the charge densities of each interface for both capacitors as a function of the applied bias responsible of the homogenous electric field. These charges densities linearly vary with the applied bias and present a thickness between 3 and 5 nm width. Scanning TEM electron energy loss spectroscopy (STEM-EELS) measurements have been carried out to understand the origin of these charged interfaces.

Figure. (a) Device structure for T-1; (b) phase map of projected electric potential obtained by electron holography for T-2; (c) Device structure of T-2; (d) phase map of T-2. Here, (b) and (d) correspond to the same regions as (a) and (c) for T-1 and T-2, respectively. Scale bars are 20 nm in (a) and (c). (e) and (f) are the phase profiles extracted from the green arrows as a function of applied biasing for T-1 and T-2, respectively.

Conclusion
We used operando electron holography to evidence and quantify charges occurring at the different interfaces in tri-layer HfO2/Al2O3/HfO2 and Al2O3/HfO2/Al2O3 nanocapacitors with TiN electrodes. An equivalent uniform electric field distribution throughout the whole dielectric stack in HfO2 and Al2O3 is observed even though HfO2 has a much larger dielectric permittivity than Al2O3. The electric field distribution originates from the presence of charges trapped at each interface. It is revealed that there is a linear relationship between the surface charge density and the applied bias, and, at each bias, the interfaces between HfO2 and Al2O3 have an equivalent trapped charge density. With unprecedented sensitivity and spatial resolution, the information gained with operando electron holography on the location of the trapped charges and on their densities provide unique insights on the functioning of nanocapacitors. Further work could be devoted to the interface charging behaviour in ferroelectric-dielectric devices.

Aims: Lung cancer is the most prevalent and mortal cancer in the world. The percentage of 85 of lung cancer incidence belongs to non-small cell lung cancer type (NSCLC). Therefore, it is crucial to develop reliable and efficient curing approach and therapeutics to treat this cancer type in order to suggest life prolonging and pain ameliorative option to the sufferers [1]. Heterocyclic compounds are within the carbon ring structure; contain hetero atoms such as Sulfur, Nitrogen, Oxygen, Selenium and Silicon into the ring. Hetero aromatic compounds form the basic structure of many drug molecules. Nitrogen-based heterocyclic compounds constitute an important and unique class among the application areas of chemistry and organic chemistry. Nitrogen-containing hetero aromatic molecules have contributed to the development of many organic synthesis protocols and different application areas in the last two decades. N-heterocyclic compounds found in nature, in addition to having physiological and pharmacological properties, constitute the basic building blocks of many biologically important molecules, including many vitamins, nucleic acids, pharmaceutical products, antibiotics, dyes and pesticides. In addition, N-heterocyclic compounds form an integral part of many pharmacologically active molecules, base pairs of DNA and RNA (guanine, cytosine, adenine and thymine) as well as purines, pyrimidines, etc. It consists of N-heterocyclic compounds such as. These nitrogen-containing heterocycle molecules with diverse properties and applications have gained importance in the field. Furthermore, electron-rich Nitrogen-containing heterocycle-containing organic molecules not only readily accept or donate a proton, but also have a variety of weak bond interactions; It can also easily establish some of the intermolecular forces such as hydrogen bond formation, dipole-dipole interactions, hydrophobic effects, van der Waals forces and π-stacking interactions of Nitrogen organic compounds [2-3].
Methods: In this work, New indole compounds were designed, which is crucial for synthetic organic chemistry and medicinal chemistry. Novel indole derivatives with NO2 have a great deal of potential for biological activity. Many pharmaceutical compounds with indole in them are on the market today. Thus, the synthesis and characterization of indole derivatives are critical to the identification of novel therapeutic compounds. The biological activity of the new synthesis molecules obtained in this study was obtained on lung cancer cells (A549) by MTT cytotoxicity test.
Results and Conclusions: The IC50 values obtained as a result of the Mtt test were found to be 4.62µm in the molecule coded EH-303 for 24 hours at the lowest concentration, while the lowest value for 48 hours was 8.17µm in the molecule coded EH-300.

Poster Group 2

Background incl. aims
Texture describes the preferred orientation of grains in crystalline materials. For characterization of texture, the reciprocal space is conventionally investigated in diffraction experiments using electrons, X-rays or neutrons as probes. In polycrystalline thin films texture is an important characteristic of the microstructure determining anisotropic properties like, e.g., charge carrier transport in bulk heterojunction (BHJ) organic solar cells (OSC). Gracing incidence wide angle X-ray scattering (GIWAXS) is a well-established method for texture analysis of OSCs, however, real space information is only indirectly accessible as averaging measure (e.g. grain size or coherence length). In contrast, electrons as probe in transmission electron microscopes (TEM) provide direct access to both real and reciprocal space while additionally delivering analytical signals for local chemical analysis. However, due to the challenge of radiation damage, electron diffraction is not well explored for OSCs. In this work we show that electron diffraction tomography (EDT) can be used to investigate the reciprocal space of polycrystalline thin films in 3D, providing information on texture comparable to results obtained with GIWAXS.
Methods
We chose two radiation sensitive BHJ OSC active layers as model sample systems. Both OSCs contain $PC_{71}BM$ as fullerene acceptor, but differ in that the donor component is a small molecule (DRCN5T) in one case and the classical polymer P3HT in the other. Large-area plan-view samples of the active layer were prepared by floating off the spin-coated film from the substrate and transferring it to a TEM grid. Real space information on the nanomorphology of the donor and acceptor phases was obtained using STEM-EELS or EFTEM as exemplary shown for the DRCN5T/$PC_{71}BM$ system in Fig. 1a. For EDT we acquired tilt series of zero-loss energy filtered SAED patterns across a tilt range of ±70° using a single-axis tomography holder (Fig. 1b). Energy filtering is necessary to suppress inelastic scattering background in particular at small scattering angles, which is critical to reveal crystallographic information on the small molecule/polymer crystallites with their nm-sized unit cells. To minimize effects of radiation damage, each diffraction pattern was acquired at a fresh sample area with electron dose well below the evaluated critical dose. From the SAED tilt series the 3D diffraction space was reconstructed with a home-developed code for 3D reciprocal space filling which is based on polar transformations (Fig. 1c). Furthermore, azimuthal averaging of the volume around qz axis was performed to obtain qr-qz reciprocal space maps for direct comparison with GIWAXS data.
Results

The qr-qz reciprocal space maps derived from EDT and GIWAXS are exemplarily depicted side-by-side in Fig. 1d for the DRCN5T/$PC_{71}BM$ film. They show excellent agreement, indicating that not only GIWAXS but also EDT is perfectly suited for texture analysis of such radiation sensitive organic films. Moreover, direct comparison of different line profiles extracted from the reciprocal space maps reveal even quantitative matching of EDT and GIWAXS data. Interestingly, the EDT data show a better signal-to-noise ratio, in particular regarding the in-plane reciprocal information, which is difficult to access with GIWAXS. From the reciprocal space maps, it can be seen that the π-stacking of the small molecules in the DRCN5T crystallites exhibit preferred edge-on and face-on orientation in the fibre like nanomorphology revealed by STEM-EELS. Quantitative evaluation of the diffraction peak characteristics yields comparable structural information in terms of crystal coherence length, mosaicity, etc..

Conclusion

In summary, we demonstrate that the texture of radiation sensitive OSC thin films can be investigated using EDT yielding results in quantitative agreement with GIWAXS. Combining EDT with real space characterization using high-resolution and analytical TEM methods provides great opportunities for a more comprehensive and in-depth analysis of OSC thin films. Furthermore, the application of the presented methodology to state-of-the-art, non-fullerene OSC systems consisting of PM6:Y6 is in progress and will be covered in the conference contribution.

Two-dimensional few-atom noble gas clusters in a graphene sandwich

Manuel Längle[1], Kenichiro Mizohata[2], Clemens Mangler[1], Alberto Trentino[1], Kimmo Mustonen[1], E. Harriet Åhlgren[1,2], Jani Kotakoski[1]
[1]Faculty of Physics, University of Vienna, Vienna, Austria, [2]Department of Physics, University of Helsinki, Helsinki, Finland

PS-01 (1), Lecture Theater 3, august 28, 2024, 10:30 - 12:30

Background incl. aims
Van der Waals atomic solids of noble gases on metals at cryogenic temperatures were the first experimental examples of two-dimensional systems [1]. Recently, such structures have also been created on surfaces under encapsulation by graphene, allowing studies at elevated temperatures through scanning tunneling microscopy [2,3]. However, for this technique, the encapsulation layer often obscures the arrangement of the noble gas atoms. When atoms are introduced into the van der Waals gap between the layers of suspended multilayer graphene the resulting structures can be directly observed at room temperature via transmission electron microscopy [4].
Methods
In this work low-energy ion irradiation has been used to irradiate suspended bilayers and double layers of graphene and hBN. Implantation parameters for noble gases from Ar to Xe were experimentally determined. Trapping occurred for Ar between 20 and 30 eV, for Kr between 25 and 60 eV, and for Xe between 15 and 65 eV. Irradiation can be carried out within the ultra-high vacuum system directly connected to a scanning transmission electron microscope [5] where the samples can be transported to a Nion UltraSTEM 100 microscope, capable of atomic-scale imaging and electron energy loss spectroscopy, without exposure to air.
Results
The atomic structure of small Kr and Xe clusters was studied via aberration-corrected scanning transmission electron microscopy [4]. We show that small crystals ($N < 9$) arrange on the basis of the simple non-directional van der Waals interaction (Fig. 1). Larger crystals show some deviations, possibly enabled by deformations in the encapsulating graphene lattice. We further discuss the dynamics of the clusters within the graphene sandwich and show that although all the Xe clusters with up to $N \approx 100$ remain solid, Kr clusters with already $N \approx 16$ turn occasionally fluid under our experimental conditions (under a pressure of ~0.3 GPa).
The figure shows the structure of small clusters. Filtered STEM-ADF images of Kr (top row) and Xe (bottom row) including all the cases where the experimentally observed structures correspond to that with the lowest energy according to the simulations for Kr (middle row) are shown.
The encapsulated clusters show dynamic behavior such as "jumps" between different positions and occasional cluster growth and shrinking. Molecular dynamics simulations were used to understand this behavior. The trapped clusters also exhibit interesting phase behavior. While all small clusters remain solid, larger clusters exhibit either solid- or liquid-like structures depending on their size, chemical element and local microscopic environment.
Conclusion
We image noble gas atoms, their cluster formation, stability and phase in two dimensions. Due to their chemical inertness, they would not condense under normal conditions, however, when trapped between two graphene sheets the atoms are forced together by the external pressure that leads to the formation of clusters [4]. This results in a simple two-dimensional van der Waals solid that can be described to a good degree simply with the Lennard Jones potential. This opens a way for the

unexplored frontier of encapsulated two-dimensional van der Waals solids with exciting possibilities for fundamental condensed-matter physics research.

Background
As nanostructured materials become more sophisticated, there is an urgent need to develop experimental methods that can map electronic band structure information on the nanoscale. The techniques that are widely used today, such as angle-resolved photon emission spectroscopy (ARPES), typically operates with a spatial resolution in the hundreds of micron range. State-of-the-art instrumentation at synchrotron radiation facilities have been developed for the purpose of improving the spatial resolution performance, such as the ARPES photoemission electron microscope (PEEM), also known as the momentum microscope, however, its band structure information still lies in the micron range. This paper presents a proposal to transform the scanning electron microscope (SEM) into a momentum microscope capable of capturing band structure information on the nanoscale. It sets out to achieve this by designing a spectrometer attachment that can capture both the energy and momentum distributions of the scattered secondary electrons (SEs) that leave the sample inside the SEM specimen chamber. SEMs at present, in their normal imaging mode of operation, function by forming a single bulk signal from the SEs that leave the specimen, and discard any information that may be contained in their energy and momentum distributions. The recent success however of acquiring accurate valence band DOS distribution information inside a commercial SEM by using a secondary electron energy spectrometer (SEES) attachment demonstrates that there is a considerable amount of under-utilized quantum state information embedded into the SE energy spectra [1]. This suggests that a further step of creating an angle-resolved SEES attachment to acquire band structure information can in principle be taken, where the SE emission angular distribution captured by a 2D image detector placed after the energy spectrometer can be used to provide wave vector information, in addition to SE energy spectra, in a similar manner to the ARPES-PEEM momentum microscope.
Methods
A direct tracing simulation method of plotting electron trajectory paths through numerically solved field distributions will be used in order to design the angle-resolved SEES energy/momentum spectrometer attachment. The simulation will investigate how best to combine the SEM's primary beam optics with the SE energy/momentum dispersion optics. The main aim will be to find viable energy/momentum spectrometer designs that can maximize the predicted image resolution, while at the same time maximizing the energy and wave vector resolutions for the band structure. The simulation will need to incorporate a viable means of acceleration of the SEs together with momentum dispersion, since 2D electron image detectors usually function by being biased to voltages of 10 kV or higher.
Results
Preliminary simulations for two different compact electric sector SE energy spectrometer designs have been made, one is a 40° deflection first-order focusing geometry, while the other is a toroidal 225° second-order focusing design. Viable acceleration/momentum dispersition unit designs in both cases incorporate two intermediate focal points before the SEs reach a 10 kV image detector, where the electrode voltages inside the acceleration unit need to change as a function of the energy

spectrometer pass energy. The predicted geometrical aberrations at the detector plane were found to be dominated by the SE energy spectrometer's exit geometric aberrations. In the case of the 40° deflection spectrometer design, the relationship between initial polar angle and detector position is predicted to be non-linear, while for the 225° toroidal design, it is predicted to be linear. However, the 40° deflection spectrometer unit design has the advantage of being simpler and smaller than the 225°toroidal spectrometer, allowing for a working distance of less than 10 mm. Further simulation details as well as other viable designs will be presented at the conference.

Conclusion

Preliminary electron optics simulation results predict that there are viable electron energy/momentum spectrometer attachment designs capable of enabling a SEM in principle to map band structure information on the nanoscale. Further considerations beyond electron optical design will be presented at the conference, such as vacuum level and signal to noise requirements.

PS-02 (1), Lecture Theater 5, august 28, 2024, 10:30 - 12:30

Background incl. aims
Phase diagrams and crystallographic defects are essential pillars for modern materials design. In recent years, increasing numbers of defect phases (also known as “complexions”) have been identified, and there are evidences on their phase transformations. Nevertheless, due to the vast variety of defects (for example, grain boundaries have five degrees of freedom), it remains challenging to study their thermodynamics in a systematic way, eventually requiring the construction of defect phase diagrams [1].
Methods
We developed a quasi in situ approach to trigger phase transformations of a single grain boundary. The same defect was monitored by atomic-resolution scanning transmission electron microscopy during various steps of triggers. We also developed automatic pattern recognition to distinguish different grain boundary structural units, and applied ab initio simulations to understand their thermodynamics.
Results
We demonstrate the phase transformation of a Mg grain boundary triggered by local Ga alloying using focused ion beam, as well as the structural evolution with time. As shown in Fig. 1, successive steps of Ga incorporation lead to phase transformations of a Mg [0001] tilt grain boundary [2, 3]. There are two aspects of the phase transformations: 1. Structural transformation from T-type (highlighted in green in Fig. 1a) to A-type (highlighted in red in Fig. 1b) structural units; 2. Formation of chemically ordered grain boundary phases as shown in Fig. 1c, d.
Conclusion
The discovered grain boundary phases and their transformations observed quasi in situ enabled us to construct a phase diagram for this grain boundary. Our developed methodology including atomic resolution imaging, automatic pattern recognition, and ab inito simulations formulates a blueprint to develop defect phase diagrams systematically and propel a new paradigm for materials design.

Poster Group 1

Background
Since the discovery of ferroelectricity in solid solutions of AlxSc1-xN in 2019, the new class wurtzite-(W)-type ferroelectrics have raised huge expectations for the introduction of ferroelectric functionality into novel transistor structures, e.g., with integrated memory. Although most of the challenges targeting the materials integrability, e.g., temperature stability, thickness scaling and epitaxy with GaN have been overcome through the past years, a fundamental understanding of the switching mechanisms has been mainly approached by theoretical studies describing the local atomic origins for switching, the switching kinetics and possible pathways. However, while visualizing local polarization switching with the scanning transmission electron microscope (STEM) seems impressive,[1] an overview onto the established polar domain structures within w-type ferroelectric thin films in support of the theoretical models remains elusive; a fact which is strongly coupled to the crystalline quality of sputtered films, whereas the accessibility of monocrystalline films grown by MBE remains limited.
Methods
We exploit annular-bright field STEM, differential phase contrast (DPC) and 4D-STEM methods to visualize the local atomic structure, polarization direction and large-scale distribution and strain of polar nano-domains.
Results
Recently, we reported on the analog switching capabilities achieved in sub-5 nm thin films and demonstrated for the first time the realization of a multiple domain state within a single grain of AlScN linked to the presence of horizontal polarization discontinuities.[2] Moreover, here we report on the first large scale observation of ferroelectric domain patterns in monocrystalline-like epitaxial AlScN films enabled by the realization of 250 nm thin ferroelectric AlScN films grown on GaN/Sapphire templates by metal organic chemical vapor deposition.[3] The analyses reveal cone-like shaped pinned interfacial domains of opposite polarization present for the “fully” polarized states even after wake-up and 400 x cycling and their spiking extension into the bulk after further biasing. The lateral dimensions of pinned and spiking domains suggest that lateral growth is complicated by the vertical grain boundaries.
Conclusions
The results will be discussed with respect to the proposed domain propagation models for w-type ferroelectrics. The existence of pinned domains with opposite polarization serve as nucleation sites which mainly reduce the overall required energy to domain wall motion rather than the formation of new nucleation sites. These results provide the next step in understanding of the ferroelectric switching mechanisms of epitaxially grown wurtzite-type ferroelectrics driving research on ferroelectric memory, power electronics and innovative computing applications.

Extending 4D-STEM based strain mapping to polycrystalline materials

Lukas Schretter[1], Mr. Jürgen Eckert[1,2], Mr. Christoph Gammer[1]
[1]Austrian Academy of Sciences, Leoben, Austria, [2]Montanuniversität Leoben, Leoben, Austria
PS-02 (2), Lecture Theater 5, august 28, 2024, 14:00 - 16:00

Background incl. aims
Four-dimensional scanning transmission electron microscopy (4D-STEM)-based techniques for elastic strain mapping have advanced significantly, offering a robust tool to investigate deformation mechanisms in materials at the nanoscale. In single crystalline materials, measurements of the reciprocal lattice vectors allow to accurately determine the full in-plane elastic strain tensor [1]. This technique exhibits high sensitivity, enabling the detection of stress fields associated with individual dislocations. In amorphous materials, like metallic glasses, 4D-STEM based strain mapping techniques have also been successfully utilized to determine nanoscale strain states in materials [2]. In contrast, for polycrystalline microstructures, lying between the two extreme cases of single crystals and amorphous materials, a technique for local nanoscale strain mapping is lacking. Although global strains can be inferred from the ellipticity of diffraction rings in selected area diffraction (SAD) patterns, this method provides only average values across multiple grains, lacking insights into the stress state within individual grains or at grain or phase boundaries. This study aims to close this gap and develop a new routine to map the nanoscale strain in polycrystalline materials, facilitating the measurement of strain fields and grain rotations during in-situ deformation of polycrystalline materials with a resolution of 2 nm.
Methods
To demonstrate the technique a 50 nm thick nanocrystalline gold (Au) thin film is used. The sample was produced by DC magnetron sputtering and subsequently underwent heat treatment at 360 °C to reduce the dislocation density present after deposition. The thin film was mounted on a push-to-pull MEMS device and in-situ tensile testing was conducted using a Hysitron PI 95 nanoindenter holder capable of recording the load-displacement data during deformation. The tensile test was intermittently halted during deformation to acquire full 4DSTEM datasets. Precession electron diffraction was employed to enhance the quality of diffraction patterns. By precessing the electron beam the experiment is shifted towards more kinematical diffraction conditions vastly improving the quality of the diffraction patterns. On the one hand, inner intensity distributions are reduced, making peak detection more precise, and on the other hand, more diffraction disks are revealed thus improving on the crystal orientation determination. The utilization of a direct electron detector and an in-column energy filter further refines the dataset quality.

Results
The resulting strain and orientation maps, obtained during in-situ deformation, affirm the feasibility of this study's objectives. Only small changes in crystal orientation were observed, consistent with the low plasticity exhibited by the nanocrystalline thin film. The limited thickness of the Au film, consisting of a single layer of grains, might also lead to less pronounced grain rotation. Nonetheless, orientation changes within individual grains resulting in subgrain structures could be detected and quantified. At the same time, the precise determination of elastic strain states in polycrystalline materials during in-situ deformation was demonstrated. Under loading, a discernible shift towards higher tensile strains was observed, with a histogram analysis revealing a gradual increase in the tensile strain spread with increasing applied load. This clearly indicates, that even in the elastic

regime dislocations are generated. Following fracture, the average strain go back to zero, however an even larger spread is measured. This shows that the increase in dislocation density and thus the broader strain distribution is not due to a measurement artifact but an actual mechanism in the material that can be quantified.

Conclusions
Atomic-level elastic strains in a nanocrystalline thin film were determined by combining concepts from single crystalline strain mapping and automated crystal orientation mapping techniques. This paves the way for future in-situ deformation experiments on industrially relevant polycrystalline structural materials, thereby enhancing our understanding of their deformation mechanisms.

Poster Group 2

Background incl. aims
Moonmilk is a secondary calcite deposit often found in karst caves, formed by nanofibers of biogenic origin, mostly on calcarenite surfaces, in high humidity and low temperature conditions. Recently, in the ancient Etruscan hypogean tombs of the necropolis of Tarquinia, moonmilk has been identified in a white patina covering the wall paintings. The presence of bacteria, promoting the calcium carbonate deposition, has opened the way to their potential use as a new and promising way for biorestoration. Our aim is to optimize this process for a successful and stable calcite deposition, because the conservation of the hypogean environment is a real challenge for restorers and conservators, and it requires a strong characterization work, both from a biological side, for the selection of the best bacteria producers of calcite, and from the applied methods, microscopies or spectroscopies, to establish a safe protocol for the evaluation of the deposited calcium carbonate and its application as an innovative restoration material in cultural heritage.

Methods
Optical microscopy, scanning electron microscopy (SEM), transmission electron microscopy (TEM) and atomic force microscopy (AFM) were used to characterize the calcite morphology, while its crystallinity was assessed using X-Ray Diffraction (XRD), Raman spectroscopy. Metagenomic studies were carried out to identify the complete bacterial community present in the moonmilk, while the choice of the most promising species capable of rapidly depositing calcium carbonate under specific conditions was performed by selecting single strains through culture-dependent method.

Results
Our research has covered all aspects of moonmilk biogenesis, from structural to microbiological studies. In our previous work we have described how Moonmilk formation occurs not only on the outer surface of the rock, but also in the inside, and how the interaction between bacteria and the rock substrate can influence the final morphology of the calcium carbonate precipitates, showing structures at both the nano- and micro-scales. Moonmilk can also be seen as a biosignature in the field of astrobiology, while for biotechnological applications, the study of the microbial community has allowed the selection of different species capable of rapidly producing calcium carbonate, making them suitable for bioconsolidation intervention.

Conclusion
Although the chemical reactions that elongate moonmilk nanofibers have yet to be determined, their origin is certainly biogenic, characterized by the presence of an entombment structure produced by a bacterial strain that detoxifies calcium ions by producing calcium carbonate. Environmental

conditions and rock substrates also have a strong influence on the final shape of moonmilk crystals. Nevertheless, the analysis of the microbial communities in the Etruscan hypogean tombs has demonstrated their very fundamental role, which can be used as a green and innovative source for bioconsolidation interventions.

Solid oxide electrolyzers and fuel cells (SOEC/SOFC) are crucial for reducing global carbon emissions. Understanding their degradation processes is key to making them more durable and cost-effective for widespread use [1]. Usually, researchers examine these cells after electrochemical tests, which limits insights into the ongoing degradation process. Our study introduces a new method that makes it possible to observe the cells in operation. This method combines the TEM characterization and the electrochemical test and correlates the structural and compositional evolution with electrochemical performance.

Methods
The presented method combines a TEM holder with a heating-biasing MEMS chip and an environmental TEM capable of introducing relevant reactive gases such as O_2, H_2, and H_2O, mirroring the operational conditions of SOEC/SOFC. We developed and utilized a special sample preparation procedure to apply three types of stimuli—heat, reactive gas, and electrical bias—directly to the SOEC/SOFC within TEM [2, 3]. The tested cells have lanthanum-strontium-cobalt oxide (LSC) electrodes and an yttrium-stabilized zirconia (YSZ) electrolyte. To study cell degradation, those cells are tested with polarization in an atmosphere of 2.7 mbar O_2 at 700 °C.

Results
STEM imaging revealed that degradation feature development in the negatively polarized LSC electrodes varies with polarization voltage. Crack formation was also observed at the interface between the positively polarized LSC electrode and the YSZ electrolyte. EELS analysis conducted simultaneously showed a Co valence state change, with lanthanum's state remaining constant. Subsequent analyses, including EDS, SAED, and HRTEM, suggested that the newly observed features in negatively polarized LSC are the result of LSC decomposing into Co_3O_4, La_2O_3, and La_2CoO_4. This decomposition process was particularly pronounced near the YSZ interface, indicating a direct correlation between structural changes and electrochemical performance.

PS-02 (2), Lecture Theater 5, august 28, 2024, 14:00 - 16:00

Background incl. aims
Microalloying elements are commonly added to high-strength aluminium alloys, mainly to promote the formation of key strengthening precipitate phases. Classic examples include Sn, Cd and In at the 100 ppm level [1], which significantly accelerate the nucleation of the strengthening phase θ' in Al-Cu alloys, thereby improving the precipitation hardening response. More dramatic is the effect of Ag additions to Al-Cu-Mg and Al-Cu-Li alloys, where new phases (Ω and T1) form in high number densities, leading to ultra-high-strength alloys typically used in the aerospace industry. In all these cases, the microalloying additions either segregate at the precipitate-matrix interfaces or precipitate first as a well-defined crystalline phase before acting as heterogeneous nucleation sites [1].
An unusual case is that of Au additions to Al-Cu, where the precipitation hardening response is enhanced and accelerated through Au dissolving inside the strengthening precipitate phase θ' [2]. This observation leads to two questions which this work aimed to address:
(1) What is the mechanism by which Au enters the precipitates and promotes their formation?
(2) Can other elements behave in this way?
Answering these questions would be useful not only for improving one's fundamental understanding of phase transformations, but also to provide a potential way of immobilizing contaminants.

Methods
This work employed a combination of aberration-corrected scanning transmission electron microscopy, density functional theory (DFT) simulations and classical nucleation theory (CNT) calculations. The microscopy was performed on a FEI Titan3 FEGTEM and a Thermo Fisher Scientific Spectra-ϕ FEGTEM, both double-aberration corrected and operated at an accelerating voltage of 300 kV in scanning transmission electron microscopy (STEM) mode. Al-1.7at%Cu-0.02at.%Au alloys having undergone different ageing treatments were examined. More details about the experimental and computational procedures can be found in Refs. [3-4].

Results
In order to understand how Au atoms are incorporated into θ' precipitates, the alloy was characterised at the very early stages of ageing. It was found that the overwhelming majority of θ' precipitates at the earliest stages of precipitation were 80-100 nm long and only 1 to 1.5-unit cell high, with ~2nm long θ" precipitate regions at the semi-coherent interfaces (see Fig. 1). The 1c-high configuration has never been observed in pure Al-Cu alloys. Chemical analysis indicated the presence of Au atoms within the structure. An atomic-scale mechanism is proposed that involves the transformation of the plentiful coherent θ" precipitates into 1c-high θ' through the incorporation of Au solute and vacancies. This mechanism is supported by DFT and CNT calculations [3,5].

The intriguing possibility that other solute elements may dissolve into the θ' phase was also examined through DFT simulations.

Conclusion
An unusual mechanism through which a microalloying element (here Au) promotes the formation of a strengthening precipitate phase (here θ') by dissolving inside it, was investigated at the atomic scale. This was found to lead to sub-nanoscale thick precipitates of aspect ratio >100. This direct transformation mechanism may also be at play in other important aluminium alloy systems, such as Al-Cu-Li with Ag additions.

Background incl. aims
Driven by potential applications in spintronics, layered ferromagnetic/non-magnetic (FM/NM) nanostructures have attracted significant interest, particularly due to efficient spin transport across epitaxial interfaces in Fe/Pt bilayers [1,2]. This renders Fe/Pt bilayers as a promising candidate material system for THz spintronic devices [3]. However, the crucial role of interface quality in these bilayers cannot be disregarded, as it significantly affects spin current transmission. Optimization of the FM/NM interfacial structure and defect density is thus a potential approach for manipulating the performance of spintronic THz emitters [4]. Here, we explore this concept by investigating structural modifications of the Fe/Pt interface, obtained by tuning growth and annealing temperatures of the bilayers. The structural properties of the resulting configurations with modified interfaces were then characterized to establish a correlation between interfacial features and the emitted THz signal.
Methods
Fe/Pt bilayers with a nominal thickness of Fe(12nm)/Pt(6nm) were deposited on MgO(100) substrates using electron beam evaporation. To maintain a constant total thickness across all samples, only the Pt layer's growth temperature was varied, to induce modifications in the Fe/Pt interface. At first, a 12 nm thick Fe film was deposited on the MgO substrate at 300°C, followed by annealing at the same temperature for 30 minutes, in all samples. Subsequently, 6 nm of Pt were deposited on top of the Fe layer at various growth temperatures, namely 300°C, 450°C and 600°C. After Pt layer deposition, an annealing process similar to the Fe layer was performed at the corresponding growth temperature of each sample. The terahertz (THz) emission properties of the resulting heterostructures were characterized using a standard THz time-domain spectrometer (THz-TDS). Initial structural investigations were conducted using X-ray diffraction (XRD). Nanoscale structural and chemical analysis was then performed using a combination of transmission and scanning transmission electron microscopy (TEM/STEM), energy-dispersive X-ray spectroscopy (EDXS), high-resolution TEM (HRTEM), and Z-contrast high-resolution STEM (HRSTEM) imaging, along with Z-contrast HRSTEM image simulations.
Results
The largest THz emission, nearly double the amplitude observed for the Fe/Pt(300°C) sample, originated from the Fe/Pt(450°C) sample, while the Fe/Pt(600°C) sample displayed negligible signal [5]. XRD analysis revealed an almost strain-free Fe/Pt configuration for the 300°C sample. In contrast, the presence of an additional $L1_0$-FePt peak in the 450°C sample suggested interfacial modifications. Furthermore, the disappearance of Fe and Pt peaks and the emergence of new peaks corresponding to the face-centered-tetragonal (fct) lattice of $L1_0$-FePt in the 600°C sample, suggested a complete transformation of the bilayer into the ordered alloy.
TEM observations confirmed distinct Fe and Pt layers with nominal thicknesses for the 300°C sample, exhibiting epitaxial growth on the MgO(100) substrate following the Bain orientation. In the 450°C sample, HRTEM analysis revealed the formation of a 2 nm thick interlayer (IL) at the Fe/Pt interface

(graphic). This IL displayed a characteristic periodic intensity modulation, indicative of a superlattice structure with high chemical ordering. Further HRTEM imaging confirmed the IL's tetragonal symmetry and identified the ordered $L1_o$-FePt structure. Moreover, the interplanar spacings of resolved lattice planes in MgO/Pt and Fe nearly matched the corresponding values of their bulk structures, implying a strain-free configuration and an epitaxial growth of the IL on the Fe layer. Z-contrast HRSTEM observations and simulations confirmed the IL's chemical ordering, with the observed intensity modulation matching a periodic arrangement of single-element Fe and Pt atomic layers in the $L1_o$-FePt structure. STEM-EDXS analysis further corroborated this, revealing interdiffusion of Fe and Pt elements confined solely at the Fe/Pt interface. For the 600°C sample, TEM observations showed complete interdiffusion and merging of the Fe/Pt layers into a single layer comprising large grains slightly misoriented to each other. The latter finding can be attributed to the presence of uneven atomic size steps and terraces on the MgO surface. HRTEM imaging revealed a periodic intensity modulation along the growth axis, indicating the formation of a chemically ordered FexPt(1-x) alloy throughout the entire layer. STEM-EDXS analysis confirmed Fe and Pt intermixing across the entire FexPt(1-x) layer, with the Pt composition decreasing from the top of the film towards the MgO/FePt interface. Notably, the $L1_o$ structure with fct symmetry was preserved regardless of the non-uniform stoichiometry.
In summary, the significantly enhanced THz emission concurred with the modified Fe/$L1_o$-FePt(2nm)/Pt interface in the Fe/Pt(450°C) sample compared to the Fe/Pt(300°C) bilayer. Conversely, the absence of the non-magnetic Pt capping layer at the Fe/Pt(600°C) sample, and despite the $L1_o$ ordered alloy formation, resulted in the suppression of the THz signal.
Conclusion
The interplay between Pt growth temperature, structural features, and THz emission in Fe/Pt spintronic bilayers on MgO substrates was investigated. High-quality Fe/Pt bilayers were achieved at 300°C. Distinct structural modifications were observed at elevated Pt growth and subsequent annealing temperatures, which were used to engineer the Fe/Pt interface, namely a 2 nm thick $L1_o$-FePt IL formed at 450°C, while a fully intermixed FexPt(1-x) alloy with ordered fct structure and alternating pure Fe and Pt-rich atomic layers superseded the individual Fe and Pt layers at 600°C. The presence of the ordered IL in the Fe/Pt(450°C) sample significantly enhanced THz emission by facilitating interface transmission. Conversely, complete intermixing and the absence of the non-magnetic Pt capping layer in the Fe/Pt(600°C) sample suppressed the THz signal. The observed enhancement in the Fe/$L1_o$-FePt/Pt trilayer configuration opens exciting possibilities for spintronic THz emitters. Furthermore, the ability to control (FM/NM) interface properties through engineered interlayers offers significant flexibility for designing future spintronic devices.

Polar Discontinuity Governs Surface Segregation and Interface Termination: a case study of LaInO3/BaSnO3

Dr Martin Albrecht[1]

Background and aims.
Interfacial polar discontinuities are a unique way to manipulate charge states at interfaces and to create novel two-dimensional electron states. The polar-nonpolar interface between ABO3 perovskite oxides offers new degrees of freedom to tune interface states by the accessibility of mixed-valence states. The commonly accepted model for the formation of a two-dimensional electron gas (2DEG) is based on the concept of charge transfer between the layers terminating the polar-nonpolar interface. To realize a 2DEG or a two-dimensional hole gas (2DHG), control of the interface is a prerequisite. When growing the heterostructures, it is commonly assumed that the surface termination of the non-polar layer controls the interface. In this work, we provide experimental evidence that polar discontinuity compensation can drive surface segregation and thus control the interface

Methods.
We study the surface termination of BaSnO3 and the interface formation between the cubic wide bandgap semiconductor BaSnO3, and orthorhombic LaInO3, by negative cs imaging and direct spectral imaging of the LaInO3-BaSnO3 interface using Scanning Transmission Electron Microscopy Energy Dispersive X-Ray Spectroscopy (STEM-EDS) with the Thermo Fisher Spectra Ultra electron microscope equipped with Ultra X EDS detector. In parallel we perform Integrated Differential Phase Contrast STEM (iDPC-STEM) technique to study the oxygen octahedral tilt at the interface, providing further insights into the compensation of polar charges at that interface. Density functional theory (DFT) calculations are used to rationalize our experimental results. The samples were grown by plasma assisted molecular beam epitaxy on DyScO3 substrates at 835°C using a mixture of Sn and SnO2 as a SnO source.

Results.
While TEM experiments of BaSnO3 bulk crystals and DFT agree that BaO is the most stable surface termination of BaSnO3 over wide range of chemical potentials, we find by EDX spectral imaging the interface between BaSnO3 and LaInO3 is terminated by SnO2 (Fig. 1). This is consistent with the presence of a 2DEG but also with our DFT calculations which show this interface to be the most energetically favorable. STEM EDX shows the presence of BaO on the surface of thin LaInO3 films indicating Ba surface segregation. Based on our DFT calculations we find that the driving force for Ba segregation is the compensation of the polar discontinuity at the interface. This compensation is an effect the gradual reduction of the octahedral tilt from the orthorhombic LaInO3 to the cubic BaSnO3 and the polar and non-polar distortions at the interface as evidenced by the evaluation of iDPC images (Fig. 2). In the case of the n-type SnO2 interface, this leads to an expansion of the out-of-plane lattice spacing at the interface which most efficiently compensates for the discontinuity. At the BaO terminated p-type interface it leads to non-polar distortions in the BaSnO3, while polar distortions remain mainly in the LaInO3 which compensate the polar discontinuity less efficiently.

This shows that in Perovskites in addition to surface energy and strain, the response of the system to compensate for the polar discontinuity must be considered as an additional driving force for segregation which may control the interface termination.

IM-05 (2), Lecture Theater 3, august 26, 2024, 14:00 - 16:00

Background

Van der Waals heterostructures have become omnipresent in materials research today as they offer sheer endless opportunities to tune properties by stacking [1]. In a Lego-like fashion, researchers combine a range of two-dimensional (2D) materials to create ever-more complex structures. However, regarding the properties of stacked 2D materials, the question arises: do we make something new or do we have a simple sum of its parts? We are still often lacking a means to study these complex stacked materials. One particular challenge that is frequently faced is that the phenomena under investigation might lie in an energy-momentum space that is impossible to access using optical methods.

Methods

Here, we show that using modern electron microscopy (EM), the energy-momentum space that becomes available can cover several Brillouin zones (BZ) in the momentum direction and several electron-volts in the energy direction. EM therefore represents an excellent opportunity to study stacked heterostructures. We combine the resolving power of the Nion HERMES instrument with the detection capabilities of a direct detector camera (Dectris ELA) to map phenomena across the BZ. Using this approach, the behaviour of phonons, excitons and plasmons can be mapped across the entire BZ. Results were compared to time-dependent density functional theory (TD DFT). To demonstrate this technique, we present the findings from a heterostructure commonly used in nanoscience research today. Hexagonal boron nitride (hBN) is the most common encapsulant for nanoelectronics and nanodevice fabrication as it is thought to not affect the properties of the TMDCs, due to its insulating character. It is known to even enhance the excitonic intensities and to decrease the excitonic bandwidth of TMDCs [2].

Results and Conclusions

Momentum-resolved EELS (q-EELS) was employed to obtain ωq maps of hBN, WSe_2 and a hBN – WSe_2 heterostructure along the high symmetry directions ΓM and ΓK of the crystal structure and the results are presented here.[3] Figure 1, a shows q-EELS as acquired of the hBN – WSe_2 heterostructure. The spectra are shown for steps in q= 0.0106 x |Γ-K-M'-Γ'| to cover the |q| distance from 1.6 to 2.2 of |Γ-K-M'-Γ|. This partially shows the detection challenge at hand. There is a significant difference in intensities at q=0 at Γ and Γ' of excitonic and plasmonic peaks compared to the finite q intensities between the Γ points. Figure 1, b shows the peak evolution between the Γ

points. This time the spectra of the same data set are shown for steps in q= 0.0106 x |Γ-K-M'-Γ| for |q| from 0.01 to 0.85 of |Γ-K-M'-Γ|. Both, excitons and plasmons and their hybridisation were studied using this approach. When comparing the energy-momentum dispersion of the main plasmon peaks, clear signs of hybridisation in the hBN – WSe2 heterostructure were observed when compared to the individual components of the heterostructure. The π- π* and the π- σ plasmon peaks were found to shift to energies that matched neither WSe2 nor hBN. Aside from the plasmon peaks, hybridisation in excitons was also investigated. hBN represents a particular challenge due to the presence of excitons that have a highly directional q dependence and lie at high q and high in energy. The presence of the fine structure at the M point as shown in Figure,b is originating from the hBN itself and is also found in hBN alone. The peak at the M point is thought to originate from vertical e-h transitions between the k points belonging to the ML line in the band structure.[4] This fine structure is absent in the ΓM direction. These findings are in excellent agreement with BSE calculations [4] as well as non-resonant inelastic x-ray scattering data from a synchrotron facility [5]. It shows that EM combined with modern direct detector technology can at least rival the results from x-ray facilities with the added benefit that the EM brings improved spatial resolution. Our results regarding the plasmon hybridisation also show that great care has to be taken when predicting properties of Van der Waals heterostructures.

PS-05 (3), Lecture Theater 3, august 30, 2024, 10:30 - 12:30

Background incl. aims
Molecular Dynamics (MD) simulations require a model for the interatomic interactions that is both accurate and computationally inexpensive. Density Functional Theory (DFT) offers good accuracy and decent computational performance for small systems, and ab-initio molecular dynamics (AIMD) is now possible based on DFT. However, many simulations require system sizes and/or simulation times that makes AIMD impossible.

Machine learning potentials can be used to generate inter-atomic potentials for specific systems, with accuracy close to that of DFT and computational efficiency close to that of classical interatomic potentials [1]. While such machine learning potentials have been used to extend the size and time scale of MD simulations to obtain adequate sampling of structures and thermodynamical properties, they suffer from the need of very large training sets and depend on the quality of the rotationally invariant descriptors used as input to the neural networks [2]. Equivariant Neural Networks change this dramatically [3], cutting down the amount of training data by several orders of magnitude while giving better accuracy. In an equivariant network, vector quantities can be used directly as input to the network and are then processed in a rotationally equivariant way.

We apply these methods to two different scientific problems. The first is heating of supported metallic nanoparticles by the electron beam in HR-TEM. The second is thermal vibrations in supported 2D nanoparticles, where recent HR-TEM studies show significantly increased vibrations near the edges of the nanoparticles [4].

Methods
We develop a simulation protocol for training Equivariant Neural Network Potentials (ENNPs) on a limited number of DFT simulations, based on the NequIP package [3]. We gradually expand the training set based on Molecular Dynamics simulations, where we use an ensemble of ENNPs to identify configurations where the uncertainty is large. DFT calculations are then added to the training data, gradually improving the ENNPs. After a few generations, we have a stable ENNP, but can still use the ensemble method to monitor the accuracy, also when simulating systems beyond the size limitations of DFT.

We simulate the heat transport between gold nanoparticles and TiO_2 support. From this we make a simple model for the temperature of the nanoparticle based on the heat deposited by the electron beam and the heat transport into the substrate. Parameters for the energy deposition by the beam are extracted from electron energy-loss spectroscopy (EELS), whereas the heat transport parameters come from the MD simulation.

Results
We simulate the heat transport between gold nanoparticles and TiO_2 support with molecular dynamics and ENNP potentials. We see that thermal transport is limited by the interface between nanoparticle and support, due to the mismatch in phonon frequencies. From this we make a simple model for the temperature of the nanoparticle based on the heat deposited by the electron beam and the heat transport into the substrate. Parameters for the energy deposition by the beam are extracted from EELS data, whereas the heat transport parameters come from the MD simulation [5].

We also simulate thermal vibrations in nanoparticles of the two-dimensional material MoS_2, supported on graphite. We use the simulated vibrational amplitudes as input to HR-TEM image simulations using the multislice algorithm and the frozen phonon formalism for vibrations. We find that edge phonon states significantly increase the vibrational amplitude not just at the edge of the nanoparticle, but several lattice constants away from the edge. This matches well what has been found experimentally by Chen et al. [4], where exit wave reconstructions were used to gauge vibrational amplitudes in HR-TEM image series of supported MoS_2 nanoparticles.

Conclusion
Equivariant Neural Network Potentials make it possible to use molecular dynamics simulations on systems with tens to hundreds of thousands of atoms, with accuracy close to that of DFT, but without the computational cost of DFT, where even a thousand atoms are a challenge. The accuracy of the potentials can be monitored with ensemble methods, and problematic configurations can be used to retrain the ENNP. The method can be directly applied to study effects of the electron beam in HR-TEM, and the role of realistic atomic vibrations in imaging.

PHOSPHO1-mNeonGreen reporter cells are a robust model to study matrix vesicle biogenesis during osteoblast-driven mineralisation

Charlotte Clews[1], Dr Scott Dillon[2], Dr Fabio Nudelman[3], Professor Colin Farquharson[1], Dr Louise Stephen[1]
[1]The Roslin Institute, The University of Edinburgh, Edinburgh, United Kingdom, [2]Yusuf Hamied Department of Chemistry, Cambridge, United Kingdom, [3]Department of Chemistry, The University of Edinburgh, Edinburgh, United Kingdom

Poster Group 1

Background and aims: Bio-mineralisation is an essential process in which bone cells initiate the laying down of mineral within the extracellular matrix (ECM) to form an organic-inorganic composite material that is both tough and stiff to support the physiological demands of bone. The delicate balance of inorganic phosphate and pyrophosphate concentrations is a major determinant of the rate of ECM mineralisation. This process is under the control of tissue non-specific alkaline phosphatase (TNAP) and PHOSPHO1, key phosphatases found in a specific set of extracellular vesicles termed “matrix vesicles” which are postulated to drive mineralisation. The biogenesis of matrix vesicles remains unclear, in part due to lack of imaging options available for such small vesicles, and the delicate nature of calcium phosphate mineral. This study aims to develop a robust imaging system that will allow us to study the mechanisms underpinning matrix vesicle biogenesis, and the process of mineral deposition within the ECM.

Methods: Mineralisation was studied in the osteoblast cell line MC3T3. The calcium-binding compound, Alizarin red was used to confirm mineral deposition, and gene and protein expression assessed via qPCR and protein across the time course. Key matrix vesicle phosphatase PHOSPHO1 was tagged with mNeonGreen and live imaging performed with pseudo-super resolution (LSM880) and super resolution (ELYRA) microscopy in live and fixed cells. Reporter cell lines were generated using Fluorescence-activated Cell Sorting (FACS) with a Bigfoot Spectral Cell Sorter, and validated for matrix mineralisation capability and fusion protein expression. Organelle markers and immunofluorescence allowed the localisation of PHOSPHO1-mNeonGreen to be followed throughout the cell.

Results: PHOSPHO1-mNeonGreen expressing cells are a robust model for imaging the intracellular stages of matrix vesicle production and biogenesis by osteoblasts. Using fluorescent PHOSPHO1 as a marker, we have followed the trafficking pathway of MV precursors in the endoplasmic reticulum to the trans-Golgi network; a process involving RAB8 vesicles and driven by microtubules. This suggests a RAB GTPase-dependant method of intracellular vesicle packaging and subsequent MV secretion by the osteoblast. Furthermore, confocal imaging shows PHOSPHO1 positive matrix vesicles appear to be released at actin-rich sites at the osteoblast cell membrane, possibly linked to focal adhesion sites. Time-lapse confocal imaging of cells surrounding mineralised nodules produced in vitro shows small PHOSPHO1-mNeonGreen objects present and interacting at the mineral-cell membrane boundary, suggesting evidence of matrix vesicle activity. Preliminary evidence with a TNAP-mKate2+PHOSPHO1-mNeonGreen double reporter line shows co-localisation of both matrix vesicle markers on intracellular objects, with object size and localisation as supporting evidence for potentially an MVB driven method of MV release.

Conclusions: PHOSPHO1-mNeonGreen expressing osteoblasts are a valuable and robust model for studying the process of bone mineralisation in vitro and allow our first insights into the intracellular steps of matrix vesicle biogenesis.

Poster Group 2

Background incl. aims
The epitaxial growth of semiconductor multilayers can benefit from the use of wafer substrates with different offcut angles. The offcut angle of a wafer refers to the angle between the wafer surface normal and the chosen zone axis. These offcuts can be precisely controlled on monocrystalline wafers such as silicon or sapphire according to the growth needs. A possible application consists in tuning the strain in the epitaxial stacks by growing the layers on single-crystal wafers with precisely controlled offcuts. However, improper wafer offcuts can lead to the undesired formation of grains, anti-phase boundaries and uncontrolled growth modes. These offcuts must therefore be accurately controlled. To characterize wafer offcuts, methods based on high-resolution X-ray diffraction (XRD) [1] and electron backscatter diffraction (EBSD) [2] can be used to characterize the wafer offcuts with sub 0.1° angular resolution. However, such measurements are complex and time-consuming (several hours). Therefore, the availability of a fast and accurate method for wafer offcut angle determination is highly desirable to enable efficient quality checks of incoming wafers and to support the growth of high-quality materials for advanced semiconductor devices. In this contribution we propose a novel workflow based on applying electron channeling pattern imaging (ECPI) techniques and successfully utilized this method to measure wafer offcut angles.

Methods
ECP is based on the diffraction of backscattered electrons (BSE) inside crystalline materials [3]. The variation of the BSE yield as a function of the incident beam direction results in a distinctive band pattern on the sample surface. This generates a set of electron channeling bands (ECB) appearing as dark lines, which forms the ECP superposed on the BSE image. For monocrystalline samples, the ECP is determined by the crystal structure and orientation. While ECP represents the reciprocal space projection onto the detector plane, the sample rotation causes the respective rotation of the ECP. The beam center can be determined by the sample rotation. Having a sample with an offcut angle deviated from the zone axis means that the ECP rotation center is not fixed to the nearest zone axis. Upon sample rotation, the ECP center forms a circular trajectory as the sample is rigidly fixed with the zone axis. As a result, the precise wafer offcuts can be directly measured from the analysis of ECP images.

Results
In this work, we successfully applied this method to Si(001) wafers with and without offcut angles. After sample loading into the chamber, the sample surface normal is first properly aligned to the primary electron beam. For the zone axis (offcut angle < 3°) present on one ECP image, a rotation series is needed to determine the wafer offcuts. During the sample rotation the whole ECP including the zone axis moves around the surface normal along a circular path. The resulting radius of the zone axis trace is determined as the wafer offcut angles. In case the zone axis is not present in the field of view, additional tilts are required to determine the zone axis position and thus the wafer offcut.

Following this approach, the achieved angular resolution is 0.1°, which agrees well with reference XRD results. With the routine procedure established in this work, the results can be obtained within 1 hour. Compared to the XRD and EBSD methods, it is faster and provides an acceptable accuracy, without requiring any specific sample preparation.

Conclusion
We demonstrate a new approach based on ECP images to determine wafer offcuts. The wafer offcut angle is characterized rapidly with an angular resolution of 0.1º. As a fast, accurate, and easy-to-use solution, the technique has wide applications, especially in the semiconductor field.

Holography with an Extended Reference in Transmission Electron Microscopy

Dr Wei Chao[1], Professor David Paganin[1], Dr Timothy Petersen[2], Professor Changlin Zheng[3], Professor Joanne Etheridge[1,2]
[1]School of Physics and Astronomy, Monash University, Clayton, Australia, [2]Monash Centre for Electron Microscopy, Monash University, Clayton, Australia, [3]Department of Physics, Fudan University, Songhu Road 2005, Shanghai, China

IM-03 (1), Plenary, august 28, 2024, 10:30 - 12:30

Background
Electron holography, first introduced in 1948 by Gabor [1], is one of the most widely used techniques for the retrieval of phase information in a transmission electron microscope (TEM). Conventionally a hologram is formed by interference between a scattered wave and a reference wave, for either an inline or off-axis experimental configuration. Holography is possible with an extended reference, arising from compact support in the specimen plane, for use in lens-less X-ray and laser applications as a dose-efficient method with a fast reconstruction process [2, 3]. In such approaches the reconstruction of the exit wave requires just one inverse Fourier transform of the recorded far-field diffraction pattern (Fig. 1a), with pre-weighted spatial frequencies. For a compact support defined by a polygonal aperture, sharp corners and edges provide innate scattered reference waves to interfere with the object wave (Fig. 1b), which can greatly simplify the mathematical form of the reconstruction process [2].
Methods
In this work, we experimentally implemented this method within a TEM operating at 300kV, choosing a square aperture as the compact support. To create effective reference waves, it is essential to ensure sharp edges and corners and to have a binary compact support defined by a sufficiently opaque aperture. To this end, a focused ion beam was used to accurately mill a micron sized square hole in an aluminum foil that was originally not electron-transparent at standard TEM operating voltages. Some residual material was left at the corner as an effective test object, the shape of which was imaged in the TEM by observing absorption contrast at low magnification. A diffraction pattern was recorded at the far field diffraction plane and used for the reconstruction.
Results
The shape of the test object was successfully reconstructed from the inverse Fourier approach using a single diffraction pattern, which provided six independent reconstructions (Fig. 1c-1d). Beyond that, we explored the possibility of applying a scanning parallel beam to overcome the limitations in the relative position and size of the object to the aperture. We also explored the comparative challenges against other instruments by considering the short wavelength of accelerated electrons, the quality of the fabricated corners, lens aberrations, centering of the diffraction patterns, far-field requirements, and detectors used. At this meeting, we will also discuss the use of a square probe forming aperture to provide optimum electron-optical configuration for this technique, as well as facilitating its implementation in a scanning mode.
Conclusions
To the best of our knowledge, this work is the first implementation of this deterministic extended reference Fourier holography method in TEM. Compared with other phase retrieval methods in TEM, the fast, real-time reconstruction process makes it promising for in-situ imaging techniques of

magnetic materials. It also shows the feasibility of determining exit wave phases from just a single diffraction pattern, with potential applications in beam-sensitive materials and biological samples.

Poster Group 1

The scanning transmission electron microscope (STEM) can capture a multitude of signals corresponding to the structural and chemical properties of a material. Examples of these methods include bright/dark field imaging, energy dispersive x-ray spectroscopy (EDS), or electron energy loss spectroscopy (EELS) [1]. EELS is of particular interest due to its sensitivity to low-mass elements and ability to determine their oxidation states, chemical bonding, and spatial distribution. An EEL spectrum is challenging to acquire due to low signals, energy spread of the beam, and the sensitivity of the detector. Furthermore, the stability of the sample is compromised due to the acquisition speed, which is a combination of signal limitations and camera read-out speed. One solution to overcome these limitations is the use of probe sub-sampling, whereby only a subset of probe locations is acquired with respect to the typical scanning grid. This has been shown to work for various STEM techniques such as 2-D imaging, EDX, and 4-D STEM [2,3]. Our goal is to apply these same strategies to EELS acquisition to increase speed whilst maintaining the structural and chemical analysis of the material.

A focused electron probe is aligned and the scan coils are connected to a scan generator to allow for a customised scanning pattern. The electron probe is then positioned at the sub-sampled probe locations and the EELS spectra acquired. For real time imaging, a subset of energy losses can be inpainted using a GPU implementation of the Beta Process Factor Analysis (BPFA) algorithm [4] on-the-fly to allow for finer alignment of the probe. For offline analysis, the data is reshaped to form a 3-D dataset where the first two dimensions correspond to probe locations, and the final dimension is a specific energy loss. This data is then inpainted using the BPFA with a 3-D patch. This process is depicted in Fig. 1.

To test this method, we simulated a sub-sampled EELS experiment using a silicon carbine sample with graphene grown on the carbon face [5]. The dataset contains 17x104 probe locations with a scan step of 0.13nm, and an energy width on the camera of 0.25eV (2048 channels). The dataset was tested using only 25% of the original data. The results (given in Fig.1) show that the data can be recovered to achieve functionally identical results to that of the original, full-sampled dataset.

This work has shown that atomic resolution EELS can be achieved with far fewer measurements of the sampling grid. By employing these methods, STEM-EELS can be faster, lower dose, and importantly accessible for potentially beam sensitive or dynamic samples. In this talk, we will present experimentally acquired data using a JEOL GrandARM2, with the goal of demonstrating practical implementation of this method.

Figure 1: Method for acquiring probe sub-sampled EELS data (left). The PC determines the scanning pattern which is connected to a scan engine to change the scan coil voltages. The EELS spectra is formed by integrating the camera signal column-wise, an this spectra is then used to form energy filtered images which can be inpainted using SenseAI's inpainting algorithm. In this case, an example of reconstructed EELS data and corresponding spectra are given. EELS spectra with zoom in at carbon π^* and σ^* characteristic peaks (top right). Example of integrated EELS maps at 285-286 eV energy loss for 25% probe sub-sampled data (bottom right).

Poster Group 2

Background and Method
The solar energy resource is still relatively under-exploited although it could cover most of our energy needs. Beyond the development of photovoltaics, there is a worldwide challenge to deploy large-scale concentrated solar thermal power plants. To address this issue, materials with high absorption in the visible range, low emissivity and good temperature resistance are required. To this end, multi-layered optical thin films produced by plasma processes are developed in the NANOPLAST project (nanoplast-project.cnrs.fr, ANR-19-CE08-0019). The stack encompasses an anti-reflective top-layer based on tantalum oxide or oxynitride, a selective absorber in the W-Si-C ternary system and a tungsten Infra-red reflective layer, denoted [Ta-O-N]/[W-Si-C]/[W]. These films are deposited by plasma-assisted technique: first Direct Current sputtering from a W target for the IR reflector, second dual reactive magnetron sputtering and Plasma Enhanced Chemical Vapour deposition, from a W target combined with different amounts (5% to 28%) of TMS-Si(CH3)4 diluted in Ar and finally reactive magnetron sputtering by adjusting O2 and N2 for Ta-O-N top layer[1].

Results
TEM characterisations were carried out to get insight into the structure and composition of the absorber, the anti-reflective top films and then the annealing of the complete system. Particular attention was paid to the influence of sample preparation. FIB (Focused Ion Beam) and ultramicrotomy were carried to get insight in the homogeneity along the growth direction of the multi-layer. In this work, we want to highlight the complementarity of both sample preparations for TEM. Actually if FIB is now well-established and allows to precisely select the region to be analysed, in the present case due to the non-equilibrium deposition conditions, FIB could also induce artefacts due to differential sputtering and/or re-deposition of elements (such as Ga) that may lead to misinterpretations. Hence by observing cross-sections prepared by ultramicrotomy, we were able to dismiss possible impacts of FIB on the observations thanks to the adhesion of the whole stack. Therefore, for the absorber, depending on the tetramethylsilane (TMS-Si(CH3)4) fraction in the Ar discharge, the quantity of Si introduced in the W-SiC:H material can be tuned with the objective to explore the possibility to prepare nanocomposite thin film composed of W nanoparticles dispersed in a dielectric SiC:H matrix. In dedicated conditions (5 and 8% TMS), FIB preparation and ultramicrotomy confirmed that W nano-crystallites incorporating C atoms could actually be identified by coupling STEM-HAADF (Figure 1.a) (Scanning Transmission Electron Microscopy - High-Angle Annular Dark Field) images, EDS mapping (Figure 1.b) and High Resolution imaging. In other conditions (20 and 28% TMS), amorphous layers are observed.

Next, the annealing of the layers was studied, first the absorber alone and then on the complete multilayer device (Figure 1.c multilayer before annealing). We thus highlighted the influence of the annealing mode (air or vacuum) and its duration on the structure, composition and therefore properties of the thin film.

Conclusion
These STEM analyses provided crucial information on the structure of the active layer and on the evolution of all layers after thermal annealing. Such information is crucial for optimizing the deposition process, especially concerning its intended application. In addition, this study illustrates the complementarity between sample preparation by FIB and ultramicrotomy. Selecting regions of interest for the FIB preparations can bring more interesting results compared to random slicing by ultramicrotomy whereas the latter allows ascertaining results observed on FIB cross-section thanks to its less damaging conditions.

Poster Group 2

Background and aim
Al1-xScxN is a group III-N based wide-bandgap wurtzite (w)-type ferroelectric. The material has been proven to be highly temperature stable as well as thickness scalable towards ultra-thin range.[1], [2] Most importantly, it is also compatible to both CMOS and GaN technologies. Therefore, ferroelectricity in Al1-xScxN is highly promising for applications such as non-volatile memory devices, neuromorphic computing, high-electron mobility transistors and even harsh environment electronics.[3], [4] However, ferroelectricity in w-Al1-xScxN is affected by high-leakage current which can become a limiting factor for its successful integration into devices.[5] In the past, standard approaches such as doping or strain was used in semiconductors to alter their properties, especially conductivitiy. Therefore, in this work we address this issue via elemental doping with Oxygen (O). During sputtering of 200 nm thin Al0.73Sc0.27N on Pt/Si templates, we introduced O via gas source into. This allowed us to tune the overall O-content in the bulk thin-film and study its underlying effect on the material structure and the ferroelectric properties of Al0.73Sc0.27N.

Methods
The structure of the doped samples was examined using X-ray diffraction, scanning transmission electron microscopy (STEM). The surface imaging and topography was performed via scanning electron microscopy and atomic force microscopy.

Results
Our results show that all the O-doped Al0.73Sc0.27N films have an overall lower leakage current density compared to the undoped films. This applies to the films even with significantly high O-concentrations ≥ 8 at.%. STEM analysis showed that the columnar Al0.73Sc0.27N crystalline grains remained unhampered with no local phase or O segregation in the bulk. In addition, as O-dopant increases, the overall polarity of the film gradually changes from entirely nitrogen to metal polarity. This modification has no significant impact on the overall (0002) crystalline texture of the film, hence allowing for better control of the as-deposited polarization state of the material.

Conclusion
Our study shows that O-doping could be a viable remedy for the leakage current compensation in w-Al1-xScxN and possibly for all other wurtzite-type ferroelectrics as well.

Poster Group 2

There has been an increasing demand for the development of innovative and sustainable energy conversion devices, aiming to replace conventional and often non-renewable or intermittent energy sources. The motivation for this drive lies in the quest for sophisticated devices, propelling efforts to discover innovative nanostructured materials pivotal in enhancing performance and safeguarding the environment. Understanding a material's compositional and structural traits at the nano and atomic levels, including the configuration of active atoms, crystalline phases, and defects, is paramount in establishing the structure-performance relationship crucial for designing new materials and enhancing existing ones. Transmission electron microscopy (TEM) is a valuable technique employed in characterizing functional nanomaterials, offering insights into crystal structures at a local scale. When combined with techniques like Electron Energy Loss Spectroscopy (EELS) and Energy-dispersive X-ray spectroscopy (EDS) it provides a comprehensive map of elemental information and atomic arrangements, facilitating insights into various promising applications. This work provides an overview of the benefits of utilizing these characterization tools for mapping layer growth, thickness, morphology, and defects of nanostructured Zinc Phosphide (Zn_3P_2) thin films and nanoislands grown by Molecular Beam Epitaxy (MBE) on substrates such as InP and 6H SiC/graphene, with a focus on solar energy applications. Atomic resolution HAADF STEM images of Zn_3P_2 thin films on InP substrates present homogeneous growth and epitaxial relationship between substrate and layer. GPA analysis displays misfit dislocations and rotated domains, and STEM EELS and XRD results indicate composition varying from 60-70% of Zn, in contrast to 30-40% of P. In the case of Zn_3P_2 nanoislands grown on 6H SiC/graphene, atomic resolution HAADF STEM images and GPA analysis reveal that some of the Zn_3P_2 grains are randomly oriented with respect to the 6H SiC/graphene substrate and also, between each other. Rotation maps reveal that, in some areas, there is a rotation of up to 1.6° of the Zn_3P_2 layer with respect to the substrate, which can be justified by the Van der Waals epitaxy between the Zn_3P_2 and graphene. These findings are corroborated by EBSD results, that indicate a most prominent orientation of the grains, and a potential small population of islands with different orientations. Rotated domains are observed, and STEM EDS attest the stoichiometry of the Zn_3P_2 grains. Samples of Zn_3P_2 on different substrates have been analysed to determine the ideal growth conditions for an effective final device. Atomic resolution STEM images have given powerful information on the crystallinity defects present on the samples. These results give the key for growth Zn_3P_2 in an optimal way and go beyond the state-of-the-art in the field of solar cells.

Characterization of LiNiMnCoO2 batteries by CT, LM, SEM and EDS for second life usability Assessment

Ute Golla-schindler[1], Judith Blau[1], Kathrin Geiger[1], Prof. Dr. Gerhard Schneider[1]
[1]Aalen University, Aalen, Germany

Poster Group 1

Background incl. aims
The most commonly used batteries at present and in the near future are Li-ion-based systems. Reliable characterization methods are the basis for improving battery properties and evaluating ageing phenomena. Our major goal is the creation of a damage catalog in which the results of the analytical investigation of aging phenomena are summarized. In this damage catalog, the damage patterns are further correlated to electrochemical data. In this way, the usability of aged cells can be classified based on the electrochemical analysis.
Methods
The analytic workflow goes from the macroscopic to the nanoscopic scale by using computer tomography (CT), light microscopy (LM), scanning electron microscopy (SEM) for imaging and Energy-dispersive X-ray spectroscopy EDS, secondary ion mass spectrometry (SIMS) for chemical analysis. Due to the reactivity of Li with air, cell opening, sample preparation and transportation from the glove box to the SEM was performed in argon atmosphere with a newly designed direct shuttle device developed for the Zeiss airlock system. The studied batteries were commercially available high voltage LiNiMnCoO2 round cells (LG21700 M50T, LG18650 HG2, Samsung INR18650 20R) aged within and outside the specifications. EIS measurements were carried out to monitor the aging process and the state of health (SOH) was determined before cell opening. In addition, cells from the same cell series were examined that were used in unknown devices with unknown applications and come out of a recycling process. This allows us to determine the degradation phenomena of batteries in daily use.
Results
CT enables to detect non-destructive macroscopic changes like, an open current interruption device (CID) created by gas formation, delamination of battery active material and cracks (Fig 1 a-d). The SEM images in Fig. 1 e, f show cross sections prepared by mechanical polishing of a cathode-side aging (e) reference cell and (f) cell out of the recycling process (LG18650 HG2). The layer thickness of the altered cathode decreases => alteration process: loss of active cathode material. The most significant change is the loss of the particle agglomeration of the battery active material. This degeneration can be assigned to high cycling rates [1]. The chemical composition of the cathode material was determined with energy dispersive X-ray spectroscopy (EDS). We obtained Ni:Mn:Co ratio close to 811. This fits to the chemical composition, which was also obtained for the LG21700M50T cell. There we performed a round robin test to proof the reliability of quantitative EDS analysis and used alternative sample preparation like Au-coating, C-coating, Ar-ion milling, transfer shuttles and yield relative deviations between the methods, Institutions and preparation techniques less than 10% for Ni and Co and less than 15% for Mn content [2]. A challenge for the analytic characterisation of Li-ion batteries is the Li detection. There the windowless Oxford Extreme EDS detector open new opportunities for qualitative and quantitative analysis. Fig. 1 (g) shows a top view SEM image of an anode of a reference cell (LG18650HG2), with marked EDS spectra positions and (h) element distribution image. The phases 1. C-rich, 2. Si-rich, 3. O-rich are visible. With the correlated EDS spectra (i-k) the Li-rich phase P3 can clearly be identified. A persistent limitation for chemical

quantification of Li in Li-ion batteries by EDS is that bonded Li cannot directly detected. Our idea is to determine the Li amount indirectly as the missing element fraction of not normalized quantitative EDS analysis. This was exemplary applied on the quantification of the Li-amount in discharged batteries cathodes. That results in a mass fraction of 6,01 ± 0,94 % for the (LG18650HG2) cell. For the alternative sample preparations of the (LG21700M50T) cell mass fractions are: shuttle: 6,0±0,5 %; air: 6,1±0,8%; Argon Ion milling: 6,4±0,6% [2]. These results agree nicely with the expectation of 6,4% for a 100% lithiated cathode material after the first formation cycle.

Conclusion

The correlative analytical workflow with CT and electrochemical characterization enables safe opening of the cell, rather artefact free sample preparation and a clear classification of the aging phenomena. This provides reliable results for the assessment of usability in the second life.[3]

Fig. 1 CT, SEM and EDS analysis. (a-d) CT images of (a) a not and (b) a released CID, (c) cell coil deformation and (d) cracks marked with red arrows. Poster Group 2

Background incl. aims
Metal nanoparticles are the key active component in a wide array of heterogeneous catalysts. Specifically, Au nanoparticles are highly active catalysts for oxidation reactions, most notably the oxidation of CO [1]. The structure of Au nanoparticles in the size range less than 5 nm is crucial for their catalytic performance, with specific facets and edge-sites key to maximizing activity and selectivity. Understanding the formation of different Au nanoparticle morphologies is therefore highly important to predicting and controlling their use at catalysts.
In this study we have employed aberration-corrected scanning transmission electron microscopy to observe the structure of Au nanoparticles formed via growth from individual sputtered atoms on amorphous carbon films. Understanding of the specific structures formed from surface-growth at different nanoparticle sizes is vital to predict catalytic performance. We aim to determine whether structures are two-dimensional or three-dimensional, whether they are spherical or hemi-spherical and whether they are amorphous or take on a distinct crystalline morphology (e.g. single crystal fcc or a twinned structure such as icosahedra or decahedra).
Methods
Gold atoms were sputtered onto a carbon film using a sputtered atom source (SAS), which produces an Ar+ beam using a cold cathode ion gun (Scienta Omicron ISE 5) typically operated at 5 keV. The ion beam strikes the gold target (99.999% pure gold) at 45 degrees, producing a secondary flux of gold atoms onto the holey amorphous TEM carbon substrate. The gold atoms were deposited at thermal energies, thus ensuring surface deposition, not implantation. Subsequently, the sputtered atoms form gold clusters on the surface of a holy carbon film (on a copper TEM grid). Enough material was sputtered to observe a wide range of cluster sizes, from single atoms to clusters consisting of >1000 atoms.
High-angle annular dark field (HAADF) images were acquired on a probe-corrected JEOL Grand ARM scanning transmission electron microscope (STEM) operated at 300 kV at the ePSIC facility at Diamond Light Source. A convergence semi-angle of 26 mrad, a beam current of 25 pA and a detector inner semi-angle of 58 mrad were used for all the data collection. Quantification of numbers of atoms in each nanoparticle was performed using a calibrated intensity measurement for single Au atoms.
Results
Au nanoparticles of size < 100 atoms were found to contain a mixture of 2D and 3D structures. In sizes < 50 atoms, approximately one third of structures were two-dimensional. This is contrary to structure predictions from DFT simulations of free-standing nanoparticles (i.e. without the influence of any support), which typically predicts three-dimensional structures are energetically favourable in structure of size > 15 atoms [2]. In novel DFT simulations of Au structures supported on a 2D carbon support, we find that 2D structures compete in energy with 3D structures up to approximately 60

atoms in size. This cut-off size of 60 atoms from DFT simulation corresponds well with our experimental data, where the largest 2D structure observed was approximately 80 atoms in size.
As nanoparticles grow to larger sizes (between 100 and 1000 atoms), they all adopt a three-dimensional morphology. This morphology was found to be approximately spherical in shape, indicating a weak interaction between the Au nanoparticle and the carbon film. The sphericity of the nanoparticles was determined through plotting of number of atoms vs diameter (as shown in the attached Figure). This result is in contrast to previous results that indicated a mixture of spherical and hemispherical structures of Au nanoparticles on a carbon film [3], which we hypothesize may be due to differences in growth rates due to different atomic deposition fluxes.
In the surface-grown nanoparticles of size 100 – 1000 atoms, we also determine the proportion of amorphous and crystalline structures at different sizes. The proportion of amorphous/glassy structures decrease as the size of nanoparticle increases (79% in the range 100-228 atoms, 54% in the range 229-435 atoms, reaching 0% in sizes above 700 atoms). The proportion of different crystalline structures also varies with size of nanoparticle, with icosahedral structures preferred at small sizes but a clear increase in the proportion of decahedral and single-crystal structures as nanoparticle size increases. The proportion of each crystalline structural isomer at different sizes closely matches previous studies of nanoparticles produced from gas-condensation cluster sources [4,5], demonstrating that nanoparticles produced using these two different methodologies are highly comparable.

Conclusion

Nanoparticles grown from single sputtered atoms on an amorphous carbon film show clear trends in morphology. 2D structures are supported up to sizes of approximately 80 atoms due to interactions between nanoparticles and support. At sizes greater than 100 atoms, nanoparticles form approximately spherical structures with no clear influence of support interactions. Surface-grown nanoparticles in the size range 100 – 1000 atoms show a distribution of crystalline structures that closely matches the distribution found in nanoparticles produced using a gas-condensation cluster source, although greater proportions of amorphous nanoparticles are observed in surface-grown samples.

Poster Group 2

Turbine blades are critical parts of turbine engines because they experience the highest temperature in the combustion zone. The thermodynamic efficiency of the turbine engine directly depends on the turbine entry temperature (TET) of hot gases; the material's temperature capability dictates the operable temperature. The current state-of-the-art, single-crystal nickel-based superalloys operate close to 80 to 90 % of their melting temperatures. There is a continuous need to design newer high-temperature materials that can withstand higher operating temperatures above 1100 °C to improve efficiency and thus reduce CO2 emissions [1].
The Mo-Si-Ti system has been explored as a potential alternative to the existing high-temperature materials because of their lower density and high melting temperatures. The eutectic Mo-Si-Ti alloy showed pesting resistance and optimal creep behavior. It has a two-phase microstructure: a body-centered cubic (bcc), solid solution consisting of Mo, Ti and Si (Mo,Ti,Si)ss and hexagonal silicide (Ti,Mo)5Si3 [2]. The creep mechanism of this alloy is yet unknown and needs further investigation to understand how the creep strain accumulates in response to the applied stress and subsequent microstructural evolution at meso- and nano-scales in the two phases.
Compressive creep tests were performed under vacuum at 1200 °C and true stress of 100 MPa to understand the creep curve with characteristic minimum and creep rate acceleration after that. To understand the microstructural evolution, the samples were crept to true strains of 1.3, 10, 20, and 40 %. Electron backscatter diffraction (EBSD) was performed to study strain distribution in two phases and identify the region of interest for transmission electron microscopy (TEM) specimen preparation by focused ion beam (FIB). The dislocations were imaged using the diffraction contrast of the selected two-beam conditions in scanning transmission electron microscopy (STEM) mode. The invisibility criterion was used to determine the acting slip planes and the character of dislocations in both phases.
The deformation of silicide was observed in 0.2 % crept samples from EBSD-kernel average misorientation (KAM) maps. Both phases undergo deformation by dislocation plasticity. The following slip systems were identified: {110}, {-121} and {-213} planes with Burgers vector b = 1/2 <1-11> in the solid solution and basal slip {0001} or prismatic slip {1-1 00} both with Burgers vector b=1/3<-1-120> in the silicide [3]. During creep deformation, the growth and coarsening of (Ti,Mo)5Si3 precipitates in the solid solution, and the nucleation and growth of solid solution precipitates in the silicide occur [3]. STEM-energy dispersive spectroscopy (EDXS) was performed to determine the local chemical composition of the precipitates in the crept samples. Figure 1a shows numerous dislocations originating from the interface in the solid solution and the interaction of gliding dislocations with (Ti,Mo)5Si3 precipitates. Whereas Fig.1b shows the formation of low-angle grain boundaries in the silicide phase, confirming dynamic recovery. The microstructural findings

were correlated with the creep curve, and the dominant creep deformation mechanisms (dislocation climb controlled creep and diffusional creep) were identified in the alloy.

Poster Group 2

Introduction

From the perspective of engineering metallic coatings, it is typically challenging to meet diverse requirements using single-phase coating materials, which often fall short in satisfying industrial needs. With metal matrix composite coatings, however, it becomes feasible to meet these diverse needs effectively. Cold spraying (CS) is a solid-state coating deposition and additive manufacturing technology that is promising for several industrial applications. It is effective in the deposition of a variety of materials, including metals, alloys, polymers, and ceramics, but also it stands out because of its compatibility with heat and oxygen-sensitive materials and capacity to create composite deposits. The CS process in general involves accelerating solid feedstock particles using pressurized and preheated gas, resulting in supersonic particle impact on a substrate. This impact leads to coating formation from deformed particles. During coating processing, impacted metal particles undergo high strain rate deformation, triggering phenomena such as grain refinement and phase transformation. These microstructural changes within CS deposits significantly influence their local mechanical properties. At the micron and submicron scale, these alterations can either enhance or compromise coating performance. Notably, phenomenon such as dynamic recrystallization occurs at interfaces—between particles and between particles and substrates—due to significant plastic deformations and adiabatic shear instability conditions during solid-state deformation. Consequently, heterogeneous microstructures might emerge at these critical locations, accompanied by localized variations in mechanical properties. However, despite numerous efforts to have a clear understanding of such featured developed in CS alloys, the precise relationship between local microstructure and mechanical behavior remains elusive for cold-sprayed composite coatings containing multiple ingredients. To engineer coatings with specific mechanical characteristics, a comprehensive understanding of microstructural features is essential. Investigating how variations in grain size, phase distribution, texture, and defects influence mechanical properties is crucial. Bridging this knowledge gap can optimize cold-sprayed coatings for diverse applications, ensuring reliability and advancing materials science.
Aluminum alloys are in high demand in light-weight structures; however, it has the potential short fall of tribological and mechanical properties. Our research team has made significant strides using cold spraying (CS) to produce compact and well-incorporated aluminum alloy (AA6061)-quasicrystal composite coatings (referred to as Al-QC). The coatings have shown superior tribological characteristics and increased hydrophobicity compared with conventional Al-based coatings and bulk metallurgical counterparts.

Materials and methods

Expanding on our previous works, our current research explores the detailed microstructural intricacies of CS Al-QC composite coatings, particularly emphasizing bonding states and particle-

particle interfaces and micromechanical properties. To achieve this, we sprayed the composite coatings using a high-pressure CS system with optimized parameters, utilizing pressurized nitrogen (N2) as the propellant gas. Additionally, we fine-tuned process settings to accelerate a limited number of particles, facilitating particles impacts on the substrates to study the deposition mechanism. Analytical scanning and [scanning] transmission electron microscopy (SEM) and (S)TEM) played a pivotal role in evaluating the microstructure of our specimens and forming scenarios regarding deposition behavior. Electron backscatter diffraction (EBSD) technique (by conventional and transmission Kikuchi diffraction TKD) was also used to collect crystallographic data from cross-sections of cold-sprayed coatings and to narrate the state of deformation. In-situ nanoindentation mapping (+1600 indents) was performed on the top surface of composite Al-QC coating, embracing both Al and QC phases, to provide detailed micromechanical insight completing the production/microstructure/properties chain.

Results and Conclusions
While QC particles mostly underwent brittle fracture and shattering upon impact, their contribution to in-situ hammering of the coating structure significantly contributed to densification and elimination of pores in the structure. Impact-induced grain refinement close to the exterior of impacted particles and alternation of texture and pattern quality due to high degree of deformation in Al-based matrix was found to be significant. Evidently, these features can endow a reliable bonding between dissimilar constituents in the composite coating structure. Presence of QC fragments turned out to provide enhanced bonding to Al particles within the composites. In addition, hardness and elastic modulus variations were found to be consistent with the heterogeneity of the microstructure induced by particle impacts and their deformation. However, intimate bonding at the interface of Al-QC and formation of interlayer enhanced the coating integrity. The findings regarding the bonding state can potentially justify the enhanced mechanical and tribological properties of composite coatings, and extended retention of the reinforcing phase in the structure under load, as observed in our previous works.

Background incl. aims
The Flash memory technology is getting close to its limit of downscaling and many researches have focused on alternative non-volatile memory technologies [1]. Mott memories, a special case of the broader class of resistive memories, are characterized by localization of their valence electrons owing to strong electronic correlations [2]. An electric field well above the avalanche threshold creates a nonvolatile conductive filament within the Mott insulator such as $(V1\text{-}xCrx)_2O_3$ [3]. Recent µ-XRD analysis of this filament shows that it is made of the same material but with smaller cell volume [4]. With the desired miniaturization of devices, the question of the actual and minimum size of this filament is vivid and requires techniques with nanometer scale resolution. Such resolution is achievable in STEM providing that a spectroscopic technique sensitive to the conductive state of the compound is used. The objective of this communication is to demonstrate that STEM-VEELS, by carefully studying the conditions and limits of the technique, indeed fulfils these requirements.
Methods
Measurements were performed using a Themis Z 80-300 kV (S)TEM equipped with a Gatan 969 EELS spectrometer. TEM lamella were prepared with a Focused Ion Beam (ZEISS, Crossbeam 550L) on V_2O_3 and $(V0.95Cr0.05)_2O_3$ single crystals (Figure a). In order to obtain data on the AFI phase appearing at low temperature in $(V1\text{-}xCrx)_2O_3$ compounds, a cryo sample-holder was used and data acquired at 95 K.
EELS spectra in the low-loss region were acquired at 300 kV with 2-10 nm pixel sizes and 0.2 ms per pixel.
The STEM-VEELS-SI were Fourier-Log deconvolved, carefully processed with PCA and the plasmon peak at around 27 eV was fitted on a limited energy range with a Drude-Lorentz model (Figure b). The precision of the method (<0.1 eV) was checked with respect to the influence of the local thickness, the crystal orientation and the possibility of presence of ice at low temperature.
Results
Our numerous experiments carried out on V_2O_3 single crystals showed that the use of the plasmon peak energy was precise enough to distinguish between the room temperature paramagnetic metal (PM) and the low temperature antiferromagnetic (AFI) phases (Figure c-d). The paramagnetic insulator (PI) and AFI phases of (V0.95Cr0.05)2O3 can also be analyzed with this method. The shift of the plasmon peak can be at least partially explained by the change in the volume density of electrons consecutive to the increase of the cell parameter in the AFI phase at low temperature. The existence/absence of a gap in the electronic structure is proven to have a minor influence on the measurement.
Other experiments on MIM devices show that the plasmon peak energy can be determined at a 5 nm resolution establishing this technique as very suitable to the visualization of (conducting) nanofilaments suggested to explain the resistive transition in these Mott-insulators.

Polycrystalline thin films and MIM devices were also studied before/after resistive switching to gain a better knowledge of the phenomenon when applied to technology relevant systems. The analysis of the considerable changes observed at the local scale will be presented.

Conclusion

By carefully setting-up parameters and experimental conditions, we demonstrated the usefulness of STEM-VEELS spectrum imaging to distinguish, at the nanometer scale, PM, PI, AFI phases in $(V_{1-x}Cr_x)_2O_3$ compounds. These temperature dependent and the ex situ characterizations of the electrical switching are prerequisites to assess which changes to expect for future in situ measurements and consequently progress on this still partly elusive mechanism.

3D fruit microstructure characterization using micro-CT imaging and deep learning-based panoptic segmentation

Leen Van Doorselaer[1], Dr. Pieter Verboven[1], Prof. Bart Nicolaï[1,2]
[1]BIOSYST-MeBioS, Postharvest group, KU Leuven, Leuven, Belgium, [2]VCBT, Leuven, Belgium

Background
Metabolic processes in plants involving transport of water, metabolic gasses, and nutrients are controlled by the three-dimensional (3D) microscopic morphology of the plant tissues. However, imaging and quantifying this microstructure, including the spatial layout of cells, pores (intercellular spaces) and vascular bundles, is a challenging task.
X-ray micro-computed tomography (micro-CT) has been proposed for 3D plant tissue imaging. This advanced imaging technique requires little preparation and resolves easily pore and cell phases due to differences in attenuation. X-ray micro-CT also covers a large field of view compared to other microscopy techniques, thus rendering more representative volumes of interest.
To quantify plant tissue morphology, the tomographic images require extensive image processing, which can become time-consuming and labor-intensive. Cell segmentation in particular is a difficult task because of low contrast in X-ray attenuation at cell-to-cell interfaces.
Deep learning (DL) is increasingly being used for complex image processing tasks in various fields. DL models can be trained to predict semantic labels where each pixel or voxel is assigned to a class label. Cell segmentation, however, is an instance segmentation task, where pixels or voxels of the same class are assigned to separate instances.
This work aims to speed up and improve 3D plant tissue microstructure characterization using X-ray micro-CT imaging and DL-based models for panoptic segmentation, which combines semantic and instance segmentation tasks. The method was developed and validated for pome fruit tissue samples.
Methods
An X-ray micro-CT dataset was collected to develop panoptic segmentation models. This dataset consisted of pairs of conventional and contrast-enhanced X-ray micro-CT images of the same tissue sample. Pear and apple fruit were sampled at three different radial positions. Different cultivars were compared. X-ray projections were acquired using a UniTom HR micro-CT system (Tescan XRE nv, Ghent, Belgium) with voxel resolution of 3 µm for apple and 2.5 µm for pear. For the contrast-enhanced scan after the conventional scan, the tissue sample was carefully unwrapped and incubated in a 10% (w/v) cesium iodide solution for 1 (all pear cultivars and ‘Jonagold’) or 2 h (‘Braeburn’ and ‘Kizuri’) while agitating every 15 min.
After reconstruction, the corresponding 3D images were registered. From the conventional scan, the binary of the cell matrix and pore space were extracted using Otsu’s thresholding. From the contrast-enhanced scan, the individual cell labels were extracted using a semi-automated cell segmentation workflow; the vasculature and stone cells were semi-manually segmented if present. Labeled images were used as ground truth for training the DL algorithm. Data was split into test, training and validation sets making sure datasets were from different fruit. Following the state-of-the art method for cell segmentation, the marker-based watershed algorithm was applied to the binary of the cell matrix as benchmark. As additional benchmark, an instance segmentation model trained on 2D data and enabling 3D prediction by averaging the 2D predictions in all orientations was included, to evaluate the cell segmentation accuracy.

Results
The panoptic segmentation model was able to segment following semantic labels: pore spaces, cell matrix, vascular bundles and clusters of stone cells (brachysclereids, only in pear tissue) and at the same time to predict intermediate representations of the instance labels, i.e. the cells, that allow cell reconstruction in a post-processing step. Thereto, it exploited the 3D extended version of the public domain Cellpose instance segmentation model, which in this study was adapted to a panoptic model after optimizing instance segmentation performance. The original instance segmentation model uses a 3D U-Net architecture to predict gradient map representations of cell instances. Following changes to this network architecture improved the instance segmentation accuracy: addition of long skip connections with direct summation, replacement of the standard building blocks with residual blocks whereby two consecutive residual blocks were implemented per layer, resulting in double the depth of the original 3D U-Net architecture, and retrieval of a style vector using global average pooling on the convolutional maps of the smallest dimension. The 3D model achieved Aggregated Jaccard Indices of 0.788 ± 0.061 and 0.889 ± 0.030 for pear and apple tissue, respectively, compared to 0.732 ± 0.075 and 0.861 ± 0.028 for the 2D model and 0.631 ± 0.134 and 0.715 ± 0.034 for the watershed-based benchmark.
The 2D instance segmentation model was able to recognize vascular bundles and stone cell clusters and exclude them from the volume-of-interest. This demonstrated the potential to expand to panoptic segmentation combining semantic and instance segmentation tasks for the 3D model. However, prediction of the semantic labels was difficult as the dataset was highly imbalanced. From the 810 training samples, 308 contain vasculature and/or stone cell clusters and if these labels were present, the occurrence based on the amount of voxels was much lower compared to the cell matrix and pore space labels. Focal loss was the most appropriate loss functions that learned the model to focus on the vascular bundles and stone cell clusters.
Conclusion
The 3D model succeeded in improving the cell segmentation accuracy over the 2D model and watershed-based benchmark. Cell segmentation remains more difficult for dense pear tissue compared to apple, but the 3D model showed greater improvement for pear tissue segmentation, reducing the difference between tissue types. The prediction of semantic labels is hindered by the large imbalance in the data. Therefore, further training wit data augmentation techniques have yet to confirm how much the focal loss can improve segmentation accuracy of vascular bundles and stone cells.

Poster Group 1

Background incl. aims
With the ever-increasing demand for high-capacity and high-power energy storage systems, solid-state batteries and their components are subject of intense research [1].The Cathode Active Material (CAM) is the main component contributing to the battery's specific energy as well as its cost [2]. State-of-the-art CAMs are transition metal oxides of the form Li (Ni_(1-x-y) Co_x Mn_y) O_2 [3]. To increase the specific energy and simultaneously decrease the cost of the CAM, high Ni contents above 95% are desired [4]. However, these Ni-rich CAMs suffer from rapid capacity fade due to degradation during cycling, forming a rock-salt-like NiO phase [5]. To detect and understand these degradation processes at the micro- and nanoscale, we investigate $LiNiO_2$ (LNO) sintered at different temperatures as a model system for Ni-rich CAMs utilizing transmission electron microscopy techniques. Here, we demonstrate the effectiveness of combining direct imaging, diffraction, and spectroscopy for investigating LNO secondary particles across various length scales. High Angle Annular Darkfield Scanning Transmission Electron Microscopy (HAADF STEM) can provide high-resolution images at atomic resolution. However, the data acquisition is locally confined to an area of a few hundred nanometers and the differentiation between similar structures of different phases may not always be unambiguous. Complementary, Precession Electron Diffraction (PED) offers detailed information about the phase and orientation of entire CAM particles with a local resolution in the nanometer range, but this information relies on previous knowledge about the expected phases as input. Thus, unknown inter- and mixed phases cannot be identified, which necessitates validation by other measuring techniques. Electron Energy Loss Spectroscopy (EELS) provides insight into the elements present in the CAM and their bonding environment, which effectively complements PED and STEM measurements.

Methods
The lamellae for TEM investigation were prepared by focused ion beam milling with a JEOL JIB 4601F dual-beam system. A beam of Ga ions with varying energies from 30 kV to 5 kV was employed to thin the samples to a thickness below 100 nm. HAADF STEM images as well as the EELS spectra were recorded on a double Cs-corrected JEOL JEM 2200FS microscope operated at 200 kV. The PED data sets were recorded on a JEOL JEM 3010 operated at 300 kV. Scanning and precession of the beam were realized by employing the NanoMEGAS ASTAR and Topspin System.

Results
During our investigation of LNO primary particles using STEM, we observed several regions that cannot unambiguously be assigned to either the layered $LiNiO_2$ phase or the degraded rock-salt-like NiO phase solely based on the high-resolution HAADF STEM images. One example is depicted in the attached Figure. On the bottom, the layered LNO phase in (210) orientation is easily recognizable. In

the center of the micrograph, a structural transformation occurs, resulting in a different structure on the top. However, from the HAADF STEM image alone it is unclear whether it is the layered phase in (211) orientation or the NiO phase in (210) orientation, as both structures exhibit nearly identical atomic positions of transition metals, which are mainly detected in HAADF STEM. In this context, a PED dataset, which correlates recorded diffraction patterns with computed diffraction patterns of the expected phases, can provide valuable information regarding the phase and orientation of the measured particle. A PED orientation map of the investigated primary particle is presented in the attached Figure. Regions of the same color exhibit the same crystallographic phase and orientation. The diffraction patterns of the layered phase better match than those of the NiO phase, confirming that the layered LNO phase is not degraded but is present in a different orientation. However, in addition to the two prominent orientations highlighted in green and orange on the PED orientation map, a thin purple region appears at the surface of the particle close to the vacuum, matching the NiO rock-salt phase. Since the sample's thickness affects which diffraction spots appear in the PED pattern, it is essential to verify whether the recorded pattern results from the presence of a different phase or from a thickness effect at the grain's edge. Moreover, the PED algorithm always matches one of the pre-input phases with the recorded data, leaving uncertainty regarding whether the proposed phase truly exists in the sample or if it resembles one of the matched phases but is actually a new, unknown phase. In this regard, spectroscopic methods such as EELS can complement PED measurements. As EELS is sensitive to the oxygen bonding environment, LNO and NiO exhibit different O EELS signatures. Particularly, the oxygen pre-peak at 527 eV is characteristic of transition metal layer oxides and absent in NiO, serving as a reliable indicator for phase determination. In the observed LNO particles, the O pre-peak is evident in the bulk but absent at the surface of the investigated grain, consistent with the PED results. Representative EEL spectra from both bulk and surface regions are provided in the Figure. By combining locally resolved STEM measurements with PED datasets of the entire secondary particle and spectroscopic measurements, we conclude that degradation of the pristine layered LNO particles occurs not only at the surface of the secondary particle but also at the grain boundaries of the primary particles within the secondary particle. The degree of degradation correlates with the sintering temperature, whereas a higher sintering temperature leads to more severe degradation.

Conclusion

We combined the results of HAADF STEM, PED, and EELS measurements of LNO secondary particles sintered at different temperatures as a model system for the investigation of degradation processes in Ni-rich CAMs. These techniques complement each other exceptionally well, providing a comprehensive understanding of the material's properties beyond what can be achieved through individual measurements alone.

Quantitative comparison of HRTEM and electron ptychography

Felix Bennemann[1], Prof Peter Nellist[1], Prof Angus Kirkland[1,2]
[1]Department of Materials, University of Oxford, Oxford, United Kingdom, [2]Rosalind Franklin Institute, Harwell Science & Innovation Campus, Didcot, United Kingdom

IM-03 (2), Plenary, august 28, 2024, 14:00 - 16:00

Background incl. aims
Electron ptychography in the scanning transmission electron microscope (STEM) has been demonstrated to be capable of providing low-noise phase images of beam sensitive materials at low dose [1]. For such materials, in particular biological samples, conventional high-resolution transmission electron (HRTEM) is the most widely used approach - usually cryo-TEM. The question then arises of whether ptychography or HRTEM offers the most dose-efficient imaging approach. While resolution can be a useful measure for comparing imaging techniques, it is dependent on the electron dose. For some electron microscopy techniques, a phase contrast transfer function (PCTF) can be defined to quantify the technique's performance with respect to spatial frequency. However, the PCTF also does not account for the dose used and is not uniquely defined for common electron ptychography techniques like the Wigner distribution deconvolution (WDD) method. In this work we introduce the detective quantum efficiency (DQE), applied to electron microscopy as a dose independent and sample independent measure of technique performance.
Historically, the DQE has been used as the ultimate performance measurement of linear systems [2] ranging from electron detectors to medical imaging systems. If the incoming noise is pure Poisson noise, it can be calculated by dividing the signal to noise ratio of the system output squared ($SNRout^2$) by the signal to noise ratio of the system input squared ($SNRin^2$). SNRin also represents the signal to noise ratio of an ideal imaging system at the same dose. In this work the ideal TEM is defined as fully coherent HRTEM phase contrast imaging with an ideal Zernike phase plate. The SNRout represents the signal to noise ratio of the various electron microscopy techniques studied. Even though the signal to noise ratio is dose and sample dependent, the DQE is not. The DQE can be thought of as the fraction of incoming quanta contributing to the image.
Methods
For the calculation of the empirical DQE, simulations were performed using the MULTEM package [3]. All 4D-STEM simulations assumed an 80keV beam energy with a probe step size of 0.15 Å and a semi-angle of convergence angle α of 22.5 mrad on a 301 by 301 grid of probe positions. A detector size of 128 by 128 pixels was assumed. Reconstructions were performed using the single sideband (SSB) method, the Wigner distribution deconvolution (WDD) method and the integrated centre of mass (iCOM) method. As a comparison, simulations were also performed for high resolution transmission electron microscopy (HRTEM). The reconstruction methods were evaluated on coherent and partially coherent datasets containing 500 noise realisations each at a dose of 4.4M e/Å². Partial coherence was simulated through the introduction of a chromatic envelope with Cc = 1.1mm and an energy spread of 0.4eV leading to a defocus spread of 5.5 nm.
The ground truth was defined as the image from a fully coherent, aberration free HRTEM phase contrast image. For the purpose of calculating the empirical DQE of the different methods, a single carbon atom served as a sample because it provided a continous Fourier transform.
Results
The SSB and WDD electron ptychography methods reach a maximum DQE of around 23% as shown in the figure. The HRTEM reaches a maximum DQE of 100% at low spatial frequencies. However,

through the introduction of a defocus spread of 5.5 nm, a rapid decay in the DQE of the HRTEM is observed. The DQE of the HRTEM decays to almost 0% at spatial frequencies above 1α while the DQE of SSB and WDD remains substantial up to 2α.
It can also be observed that the DQE of both SSB and WDD shows almost no change through the introduction of the chromatic envelope.
The DQE of iCOM follows the same shape as that of SSB and WDD. However, across all spatial frequencies it is 3-5% below that of SSB reaching its maximum at around 18%. It is interesting to note that even with partial incoherence introduced SSB outperforms fully coherent iCOM.
Conclusion
In this work we have successfully defined a dose and sample independent framework in which HRTEM and electron ptychography can be compared against each other using the DQE. We showed that in the absence of partial incoherence, an HRTEM can achieve a DQE of 100% while SSB and WDD ptychography have a maximum of around 23%. However, the introduction of partial coherence shows the weakness of the HRTEM. Considering a defocus spread of 5.5 nm the DQE of HRTEM remains close to 100% at low spatial frequencies but decays rapidly at higher spatial frequencies.

Poster Group 1

Background incl. aims
The efficient detection and analysis of micro- and nano-particles is a topic of increasing importance, both due to their wide spread use in industrial process and the increasing issue of environmental pollution, especially with micro- and nanoplastics [1]. We specifically focus on the analysis of micro- and nano-particles in liquids, most commonly water. Here we aim to combined the advantages of microscopy based methods, which typically measure on the “single-particle” level, but require sample preparation and can be cumbersome to use for the measurement of a larger number of particles, with the low sample preparation requirements and high-throughput of ensemble based methods [2]. To this end, we combine OptoFluidic Force Induction (OF2i®) with a Raman microscopy based setup. OF2i® uses a laser beam to trap particles inside a flow cell and determines both particle sizes and concentration by observing the scattered light and acceleration of single particles through the measurement cell with an ultramicroscope setup. Raman microscopy can determine the composition of both organic and inorganic particles (but not metals), by observing the inelastically scattered light of a laser focused onto a particle. A multimodal OF2i®-Raman setup can therefore provide the best of both worlds, allowing for high-throughput “flow-through” measurements with little to know sample preparations, whilst providing analytical information on the single particle level.

Methods
The multimodal OF2i-Raman setup is based on a conventional OF2i instrument (BRAVE B-Curious). The conventional OF2i consists of a 2D optical trap in a microfluidic flow channel and an ultramicroscope observing the elastically scattered light perpendicular to the laser propagation direction [3]. The ultramicroscope is modified into two beam paths (elastic and inelastic scattering), with the elastic path functioning as a regular OF2i and the inelastic path is coupled to a Raman spectrometer. The Raman spectrometer is operating in a mode similar to “line-illumination” imaging mode in Raman microscopy, thus allowing for the simulations Raman measurement of particle spectra along the particle flow direction. For the optical trap a linearly polarized laser (wavelength: 532nm/power up to 2W) is used either as a Gaussian beam or a doughnut shaped Laguerre-Gaussian.

Results
We have consturcted a OF2i-Raman setup prototyp and have achieved a prove of principle of the setup for the detection of both organic (polystyrene, see graphic) and inorganic (TiO2) particles. In order to achieve the highest possible sensitivity in the Raman measurements we had to modified the standard OF2i-approach, which uses a laser beam propagating in the flow direction to accelerated the trapped particles, to one where the laser beam is propagating against the flow direction, thus slowing down the particles and allowing for longer accquisition times in the Raman. For challaning particles (small particles, small Raman crosssection) this approach also allows us to fully trap specific particles, in the focus of the Raman-setup. Furthermore, the modified OF2i-Raman-approach has been used for hyphenation with ICP-MS [4].

Conclusion
With our novel approach combining OF2i and Raman microscopy, spectroscopic analysis of micro- and nanoparticles, on the single particle level, is possible with high-throughput, directly in water (or other liquids) and minimal sample preparation. We are thus convinced that this approach can contribute to the growing research into environmental pollution with microplastics as well as other fields of research on the topic of micro- and nano-particles. In addition, the potential of our new approach for further hypenation with complementary analytic techniques has already been demonstrated [4] and we are convinced that combing different analytical techniques in a seamless way is the way forward towards a universal analytical tool box for nanoparticles.

Poster Group 1

Background
Disordered rocksalts (DRS) have a rocksalt structure, with the disordered nature relating to compositional disorder, predominately on the cation sublattice, which generally contains lithium and some combination of transition metals. In some instances, disorder can also be present in the anion lattice when fluorine is added to the composition.
They have emerged recently as an alternative to layered cathode structures in Li-ion batteries. These materials have attracted commercial and scientific interest because of their potential to enable fully cobalt-free, high-energy density cathodes [1]. DRS cathodes do not have a well-defined layered structure through which lithium can move in and out of the material as in most well-established commercial materials. Instead, lithium is understood to percolate through the material by hopping from one octahedral site to the next, via the tetrahedral interstitials. The energetics of the tetrahedral interstitials are proposed to be related to the surrounding ions [2]. This process can only occur when a network of such sites is formed on a length scale matching the particle size. Short-range order (SRO) and its inherent correlation with local arrangements of atoms play a critical role in determining the ability of lithium to migrate reversibly through the material [3]. This study aims to demonstrate the capability of STEM imaging methods to provide insights into the local arrangements of atoms associated with the SRO.

Methods
The presence of highly structured diffuse scattering in electron diffraction patterns, such as that observed in Figure 1a, has been widely used to indicate the presence of SRO in these materials [3]. Still, to the best of our knowledge, no precise understanding of the nature of this ordering has been achieved. Diffuse scattering of a similar nature has been observed in other materials understood to contain SRO; and is widely discussed as being related to correlations of lattice sites associated with polyhedral geometries, such as the octahedral cluster depicted in Figure 1b. These polyhedra are understood to correspond to three-dimensional loci in reciprocal space, from which the electron diffraction of a particular reciprocal lattice plane can be understood as the intersection of the lattice plane with the three-dimensional loci, illustrated in Figure 1c [4]. However, electron diffraction does not give precise local information about the distribution of the ordering within a particle nor does it identify the composition of the correlated clusters. The Z-contrast nature of annular dark field (ADF) imaging is demonstrated to be sensitive to the SRO by the presence of the diffuse scattering features in the Fourier transform of ADF images (Figure 1d and 1e).

Results
In this study, we develop a method of understanding these features by suppressing contrast from the Bragg reflections in the lattice from ADF images which show intensity variations in neighbouring atomic columns. Extending on this, we demonstrate a real-space method based on calculating the inverse Fourier transform of the square modulus of the Fourier transform, which we refer to as a

correlograph, to identify the nature of the correlations in real space, as demonstrated in Figure 1f. The inset region in Figure 1f shows the correlograph and identifies both positive and negative correlations on a filtered image where the lattice contrast has been suppressed.

Conclusions

The method proposed in this study allows distinct differences in the SRO to be interpreted from the ADF images that arise from composition variations. These differences in terms of the homogeneity of the SRO and composition of the clusters can't be distinguished from the diffraction data alone. This method enables us a new understanding of the SRO and, in turn, a link between the structural units of the SRO and the ability of the materials to sustain lithium percolation.

IM-05 (3), Lecture Theater 3, august 27, 2024, 10:30 - 12:30

Scanning ion microscopy in combination with transmission ion energy-loss spectroscopy (IELS) for low-energy ions is a promising field of study, which seeks to provide complementary information to that of more conventional techniques like electron energy-loss spectroscopy (EELS) in scanning transmission electron microscopy (STEM). In contrast to electrons, ions are capable of both capturing and losing charge, allowing for charge exchange and neutralization processes [1]. In addition, while primary electrons are capable of exciting plasmonic and electronic states, as well as ejecting core-shell electrons, ions are further capable of temporarily merging their electron orbitals with those of the sample's atoms (potentially ejecting ion-induced Auger electrons), as well as ejecting sample atoms (measurable using mass spectrometry), creating unique signals not available to electron beams. The energy lost by the ions during these sample interactions can be measured as an increase in the time-of-flight (ToF) from the sample to the detector. Furthermore, the scattering pattern seen on the detector contains detailed information not only about the crystal structure, but also the trajectories of the ions within that structure [2]. By combining spatially resolved ion energy-loss and scattering information, we can thus create a rich 5D dataset: 2D position on the sample plane, 2D position on the detector plane, and finally ToF information for each ion or neutral collected. He+ ions are chosen for this work as they are particularly well suited to low-energy transmission ion microscopy due to their relatively small scattering cross-section (allowing for thicker samples) and their relatively low damage to the sample.
Our work at LIST focuses on low-energy (up to 30 keV) scanning transmission helium ion microscopy (STIM) coupled with ToF to analyze the angular and energy distribution of the transmitted helium ions and neutrals. Two prototype instruments are being developed: one based on a commercially available gas-field ion source (GFIS), which can achieve sub-nm probe sizes, and a second based on a commercially available DuoPlasmatron source with a probe size of <300 nm. Each prototype is equipped with a high-sensitivity microchannel plate (MCP) with a delay-line-detector (DLD), capable of measuring the exact location and timing of single ion or neutral impacts. However, due to the complexity of modifying the GFIS column to perform beam pulsing, it is not yet capable of TOF measurements (i.e. only capable of 4D datasets), while the DuoPlasmatron source comes with pulsing/blanking plates. The DuoPlasmatron based prototype also has a high flexibility in the instrument configuration, allowing for post sample ion deflection to determine the fraction of ions neutralized within the sample, as well as the ability to vary the post-sample flight distance.
Using a previous iteration of the DuoPlasmatron system, we have been able to create images by generating contrast from the total counts, the ratio of neutrals to ions, the scattering angle, and the energy loss (other criteria could also be envisioned with such a rich dataset). As each pixel in the sample image contains a full ToF spectrum and a scattering pattern, we have developed python software based on matplotlib and pandas with a graphical user interface for interactive plotting of sample images, detector images, and ToF spectra based on flexible combinations of ROI selections, in

order to intuitively explore the 5D dataset. We have also compared our experimental scattering angle and energy-loss results from this instrument to SRIM simulations [3].
In parallel with the development of these instruments, we have also performed stationary-beam transmission ion experiments at the mature time-of-flight medium energy ion scattering (ToF-MEIS) beam line at Uppsala University, where extremely fast blanking speeds (below 1 ns) and higher accelerating voltages (up to 350 kV) are possible (Rev. Sci. Instrum. 83, 095107). Here we have seen differences in both the scattering pattern and ion energy distribution based on the direction of the beam passing through a thin single-crystal Si film with an amorphized layer on one side. In the case where the ions pass through the amorphous layer and then the crystalline layer, we observe a distinct crystalline scattering pattern, but a relatively broader energy distribution. For the inverted sample, where the ions instead pass through the crystalline layer first, we observe an apparently random scattering pattern, but a relatively narrower energy distribution. Ion channeling simulations performed with IMSIL [4] at TU Wien corroborate the dependence of both the energy and scattering distributions on the orientation of the sample with respect to the beam. These results are also in agreement with the simulation and experimental results of Holenak et al. demonstrating that a disordered surface layer can redirect incident ions into planes and channels, instead of randomizing their trajectories [5].
The authors acknowledge funding from the Luxembourg National Research Fund (FNR) AIMSTHIM2 (C21/MS/16215748) and STHIM (C16/MS/11354626), for the experimental work performed at LIST, as well as funding from the EU Horizon 2020 programme through the RADIATE project for the experimental work performed at Uppsala University.

Abstract
Background incl. aims
Ammonia dehydrogenation is the key process for completing the ammonia-based clean energy production-utilization cycle, and Ru/CeO2 has been known as one of the most active catalysts for ammonia decomposition reaction. Here, the catalytic activity of Ru/graphitic carbon nanofibers (GNFs) not only shows higher activity compared with Ru/CeO2 under the identical condition, but also continues to increase gradually over the time. Understanding the evolution of Ru nanocluster on GNFs (Ru/GNFs) is necessary for developing highly active and durable catalysts for ammonia decomposition reaction.
Methods
Loading of the catalyst onto the Transmission Electron Microscopy (TEM) grid for the Identical Location Scanning TEM (IL-STEM) experiments was carried out as follows: suitable GNFs was drop-cast on a holey carbon-coated Au grid (Agar scientific, H7 finder grids), where Ru nanoclusters were then deposited onto GNFs coated Au grid by magnetron sputtering. Samples are imaged by a JEM-2100F TEM (JEOL, Japan) operated at 200 kV, which is equipped with a spherical aberration (Cs) probe corrector for STEM (CEOS, Germany). The probe convergence angle is 19 mrad and the collection angle range of the annular dark field (ADF) detector is set from 31 to 82 mrad. aberration-corrected STEM (AC-STEM) images are captured with an electron probe size of 8 C and a pixel dwell time of 38 µs with a scanning area of 1024 × 1024 pixel. The bright field (BF) detector is also used in parallel. X-ray photoelectron spectroscopy (XPS) data was collected using a Kratos AXIS Ultra DLD instrument using monochromated aluminium Kα emission at 120 W and a Thermo Scientific K-Alpha X-ray spectrometer with a monochromated aluminium source at 1486 eV.
Results
A series of AC-STEM images of Ru nanoclusters at the identical location GNFs under different conditions have been recorded to track the evolution of the Ru nanoclusters. It clearly shows the sizes of Ru nanoclusters are relatively small and there are some single atoms exist in as-prepared material. After reduction process, the fraction of single atom increased, and the nanoclusters grown with increased size variation. After 3 hours of the ammonia decomposition reaction, the single atoms seem absorbed into clusters. To quantify the evolution of Ru nanoclusters, the images have been analysed with a custom python program. The average size of the Ru nanoclusters increases after the reduction process, from around 1.04 (as prepared) to 1.34 nm, and after 3 hours of the ammonia decomposition catalysis it still maintains around 1.34 nm. The size evolution suggests that the Ru nanoclusters agglomerate during reduction process to reduce the surface energy. Additionally, the

nearly identical size of Ru nanoclusters after reduction and under ammonia decomposition reaction indicates that the Ru nanoclusters are stabilized by GNFs.
After reduction, the Ru nanoclusters show hexagonal close-packed (hcp) structure, which is maintained after 3 hours catalytic process. The development of the crystallinity of the Ru nanoclusters during the heating treatment is also validated by IL-STEM observation. The crystallinity of diffuse, almost amorphous Ru nanoclusters increases only slightly after the reduction process, and significantly more after 3 hours of catalysis. To quantify the crystallinity of the clusters, relative intensities of the strongest reflection spots in FFT of the images of different nanoclusters are analysed. The intensity is found to be the strongest for the crystalline, medium for semi-crystalline and low for amorphous forms of the clusters. The crystallinity of Ru nanoclusters during the reduction treatment has shown a general tendency of increasing and further enhancement after 3 hours of catalysis.
As the catalysis of the ammonia decomposition reaction proceeds for a longer period (12 hours), the ratio of single atom decreases further compared with 3 hours, while the average diameter of nanoclusters has not increased further after a longer catalysis time. The development of the hcp structure of the Ru nanoclusters after 12 hours is also validated by AC-STEM observation.
The strong binding energy of nitrogen on metals means that the rate-determining step in the ammonia decomposition reaction is recombination N atoms to N2, while the hcp Ru exhibits the lowest activation energy for the N2 desorption reaction, so it possesses the highest activity compared to other structures for low temperatures ammonia decomposition reaction. By activating the Ru/GNFs catalyst during the reaction process, the Ru nanoclusters evolve into faceted hcp structures, which lead to increased density of B5 sites (catalytic active sites with favourable electronic and geometric properties for rate-determining step). The electronic density on the Ru nanoclusters also increases during the catalysis, which has been indicated by the clear evidence of N present in the spent catalysts.
Conclusions
The Ru/GNFs, where Ru nanoclusters are deposited onto GNFs by magnetron sputtering, has shown as a highly active and self-improving catalytic behaviour for low-temperature ammonia decomposition reaction. A series of AC-STEM images of Ru nanoclusters at the identical location GNFs at different stages of the reaction process have been recorded to track the evolution of the Ru nanoclusters at the atomic level. The data shows that activation of the as-prepared Ru nanoclusters on GNFs at 450 °C induces a structural change from amorphous nanoclusters to the faceted hcp morphology, increasing the density of B5 sites, which are known to serve as active sites and exhibit high activity in ammonia decomposition reaction. This study demonstrates that GNFs stabilize the Ru nanoclusters and B5 sites in hcp structure which is crucial role for the enhanced catalytic activity. These results may open a path for designing highly active and durable catalysts for ammonia decomposition reaction.

Improving Control Signals for Interference Gating

Simon Gaebel[1,2], Hüseyin Çelik[2], Dr. Christian M. Günther[2], Dr. Tolga Wagner[3], Prof. Dr. Michael Lehmann[2]
[1]Max-Born-Institut, Berlin, Germany, [2]Technische Universität Berlin, Berlin, Germany, [3]Humboldt-Universität Berlin, Berlin, Germany

Poster Group 2

Background incl. aims
Time-resolved methods in transmission electron microscopy have become increasingly important in recent years. For off-axis electron holography, one of the most established phase-resolved methods in electron microscopy, interference gating (iGate) [1], has proven to be the most effective implementation for dynamic studies, achieving a time resolution of 25 ns [2]. It is based on the targeted elimination of interference patterns for a large part of the period, synchronized with a periodic process to be investigated. By disturbing the interference pattern with uniformly distributed phase shifts between object and reference wave, the interference pattern is smeared, while the measurement remains undisturbed for a short time (gate), allowing a time-resolved interference pattern to build up.

Methods
Based on theoretical approaches to describe the contrast-influencing properties of gating signals, a novel approach for square-wave-based control signals is developed and presented. The basic idea is that to cancel the interference it is sufficient to superimpose two identical interference patterns, which are shifted only by a constant phase shift of exactly pi to each other. This can be realized by simple square wave-based signals, thus avoiding the signaling problems associated with complex signal shapes (e.g. noise-based control signals) as used so far. The main advantages of this approach are, on the one hand, that such signals can be realized with common electronics (e.g. fast square wave generators) and, on the other hand, that the improved control signal requires a significantly lower amplitude to cancel the interference pattern. The presented adaptations are tested by means of time-resolved electron holography on a nanostructured coplanar capacitor at the FEI Titan 80-300 Berlin Holography Special.

Results
Compared to the noise-based control signal, the developed square wave-based control signal provides matching results when sampling a sawtooth signal applied to the capacitor at a time resolution of 100 ns. Due to the advantages mentioned above, it is already possible to achieve a time resolution of less than 2 ns using a conventional digital pattern generator (DG2040). With this it is possible to investigate the switching behavior of the capacitor at a repetition rate of 50 MHz. The attached figure shows the slope of the time-resolved phases (orange). Compared to the expected switching behavior (dashed green line), these reveal overshooting, which is most likely caused by signal reflections.

Conclusion
According to the results, the square wave-based control signal proves to be superior to the previous noise-based control signals and will be indispensable in future implementations of interference

gating, particularly due to its ease of implementation. Time resolutions in the picosecond range are now within reach thanks to this innovation.

Background
Dimensionality and size profoundly influence material properties, driving diverse functionalities and applications. Current nanomaterials research focuses on specific dimensionalities like fullerene (0D), carbon nanotube (1D), graphene (2D), and graphite (bulk 2D), each offering distinct traits. Combining materials with different dimensionalities can unlock new functionalities, leading to "mixed-dimensional heterostructures." The crucial role of interfaces in these structures often lacks precise control.
We aim to utilize two-dimensional layered materials as substrates for growing nanostructures through van der Waals (vdW) epitaxy. This approach targets mitigating strain and stress issues inherent in conventional covalent epitaxy.[1] By creating well-defined mixed-dimensional heterostructures, we aim to enhance the heterostructure functionalities.[2] Here, we present the study of the growth of $CsPbBr_3$ perovskite nanoplatelets on low symmetry layered $ReSe_2$.
Methods
The mixed dimensional heterostructure of $CsPbBr_3$ on two-dimensional $ReSe_2$ was synthesized in a home built chemical-vapor-deposition system composed of a three-zone tube furnace. The structural and chemical characterization of the heterostructure was done by scanning and high-resolution electron microscope (Sigma 500 SEM, Zeiss and HRTEM-Themis Z, respectively). Band alignment characterization was done by X-ray photoelectron spectroscopy. Nanotribology studies were performed using AFM and in-situ combined AFM-SEM system.
Results
Mixed dimensional heterostructure of $CsPbBr_3$ platelets on $ReSe_2$ shows the growth of well-aligned and elongated $CsPbBr_3$ nanoplatelets. The optoelectronic properties the mix-dimensional were characterized, revealing type-I band alignment. In addition, tribological studies[3] were conducted by monitoring the force required to push the nanoplatelets along the surface. This revealed an anisotropic sliding effect when pushing rectangular platelets along their long and short axis. This effect is correlated with the commensurability of the two lattice structures in each direction, as revealed by HRTEM analysis. Sliding along the surface can also be hindered by atomic steps and defects, which are easily detected by scanning electron microscope. Therefore, sliding experiments were performed in situ in a combined AFM-SEM system and were compared to an ambient AFM system. These comprehensive experiments enabled a detailed view of the surface and $CsPbBr_3$ platelets before and after sliding, providing a rapid overview of the sample.
Conclusions
The mixed dimensional heterostructure of $CsPbBr_3$ platelets on $ReSe_2$ shows well-defined epitaxial relations. The heterostructure interface was probed to study the charge transfer mechanism and the epitaxial relations. The anisotropic growth of the platelets manifested itself in both TEM characterization and tribology experiments, revealing an anisotropic sliding effect of the $CsPbBr_3$ over the $ReSe_2$. Overall, this work presents a route for guided growth of mixed-dimensional

heterostructures using vdW epitaxy and characterizes the vdW bonding nature within the heterostructure.

Poster Group 2

Noble metal nanoparticles such as Au and Pt are well known and widely used for their catalytic properties. Because of the cost of these noble metals, different strategies are pursued to find surrogates to noble metals in catalysis. Emerging and promising approach is to play with NPs of transition metal carbides. Among the candidates for these substitutions are WC NPs [1] ,Mo2C nanoparticles [2] or Co6Mo6C2 combined with graphitic carbon for oxygen reduction. The aim of this study was to develop a route for synthesizing bimetallic carbides NPs in two-step process and the originality of this approach lies in the choice of the metallic precursors.
Octacyanometalate-based networks (OCMs) are 3D metal networks in which the metals are linked together by CN bridges. A water-based surfactant-free synthesis was shown to be applicable for the synthesis of PBAs [3]. It is versatile enough to get networks composed of the combination of any transition metals of our choice. The desired 3D compounds are obtained by mixing a solution of cyanometallates involving one kind of metal (M' = Mo or W) with a solution of another metallic salt of the second metal (M = Co). To turn the metalate network into metallic carbide, the OCMs undergo heat treatment, under inert atmosphere as the procedure used by Aparicio et al [4].
In bimetallic particles, different types of η-carbides-type structures were evidenced in our sample. Co3Mo3C, Co6Mo6C, and Co2Mo4C from the Co-Mo-C system. Co3W3C (fig 1), Co6W6C, Co4W2C, and Co2W4C from the CO-W-C system. These compounds were identified by combination of Transmission Electron Microscopy, high resolution STEM/HAADF imaging of individual NPs (fig A), EDS analysis (fig B-C), and compared simulated (fig D) and experimental HAADF-STEM image (fig E). The size of these carbide nanoparticles is 5 nm in average. Along with η-carbides, the presence of monometallic carbide nanoparticles such as Mo2C and WC has also been observed. The pyrolysis temperature is an important factor in the formation of nanoparticles. Indeed, a treatment at a too low temperature, < 700 °C for Co-Mo system and 800 °C for Co-W system will not enable the complete transformation of the precursors. Beyond these temperatures, η-carbide nanoparticles account for the majority of the nanoparticles observed (> 60%).
Co3M'3C, Co6M'6C, Co2M'4C (M' = Mo or W), and Co4W2C, metallic carbide nanoparticles were successfully synthesized by thermal decomposition of Cs-Co-M' precursor octacyanometalate networks. Their presence in significant proportions in a definite temperature range attests for the efficiency of the synthesis route by thermal decomposition of OCM. The strength of this method also lies in the wide choice of metals that can be used to fabricate octacyanometalate-based networks and thus potentially the wide choice of carbides nanoparticles that could be made easily and rapidly accessible

Background incl. aims
All-solid-state lithium-ion batteries offer higher capacities and improved safety compared with batteries that make use of a liquid electrolyte in part because of their potential to utilise a lithium metal anode and a solid ceramic electrolyte. Changing to a solid-state electrolyte removes many of the safety concerns surrounding lithium-ion batteries that are associated with the volatile and flammable liquid electrolytes currently used. An initial lack of understanding of the mechanical and diffusion properties of lithium metal means attempts to use pure lithium metal as the negative electrode (anode) have failed at the high currents and rates required for powering electric vehicles (EV). In this work we aim to solve these issues through alloying lithium to produce anodes with novel microstructures that can achieve the currents and rates required for EV application. Understanding how these new materials function as anodes requires characterisation of the behaviour of lithium entering and exiting the material, requiring microscopy up to atomic resolution with spectroscopy [1]. We study three lithium alloy systems (Li-Ca Li-Sr, and Li-Ba) for which no transmission electron microscopy has so far been reported in the literature.
The overarching aim of this work is to develop a deep understanding of the materials properties and mechanisms behind the premature short-circuiting and failure of solid-state batteries. A proposed route for initiating dendrite growth that leads to short-circuit failure is a non-uniform electric current at the anode-electrolyte interface caused by void formation during stripping [2]. We propose an alloy anode material as a solution that on stripping will retain full interface contact between the anode and electrolyte during cycling thus stopping void formation at the interface between the electrode and electrolyte. This is achieved by producing an anode from a two-phase material consisting of the lithium metal, to be cycled, and a lithium intermetallic that remains as a three-dimensional scaffold to provide both electrical and ionic contact between the current collector and the solid electrolyte throughout cycling. This concept was shown to be viable by Jia et al [3] electrochemically cycling the Li-Ca system with a liquid electrolyte. However, development of these alloys requires a full understanding of the mobility and bonding of lithium through the distinct phases and the microstructures produced by manufacturing and how those change with cycling.

Methods
A combination of plasma focused ion beam milling and scanning electron microscopy energy dispersive x-ray characterisation are used for the identification of the two-phase material on a larger scale and to identify regions of interest for the production of transmission electron microscopy lamella. Given the air sensitive nature of these materials, anaerobic sample preparation and transfer was used between instruments. Transmission electron microscopy and electron diffraction are used confirm the creation of the desired phases. Like most battery materials these lithium containing phases and the lithium metal that surrounds them are highly beam sensitive. Preliminary data shows that the pure lithium metal phase loses crystallinity (as observed by disappearance of electron diffraction spots and directly imaged lattice planes) when illuminated with a dose rate greater than 6 e/A2/s.

Results
Energy dispersive X-ray spectroscopy shows the material as cast has two distinct phases one containing the group two element and one without. Standard EDX spectroscopy cannot detect lithium meaning that the composition of alloys cannot be determined at this step and additional techniques are required for phase characterisation. Transmission electron diffraction from extracted lamella shows that the anode materials formed have two distinct crystallographic phases, in each case containing a lithium metal phase and a lithium intermetallic. The three intermetallic phases studied range in complexity from large face centre cubic (Li23Sr6 F m -3 m) to large hexagonal (CaLi2 and Li4Ba P 63/m m c). The microstructure varies dependent on the alloying element and the local composition during solidification with the width and homogeneity of the scaffold phase reducing with reduced group two element concentration. Preliminary cycling data shows that the material is capable of working as an anode and characterisation shows that the intermetallic scaffold remains after lithium has been stripped from the electrode. The graphic shows that the removal of the lithium metal is observed to be preferential to the conversion of the intermetallic and voids form first in the metal regions closest to the electrolyte. In the graphic the voids are highlighted in red at the top of the anode after a partial strip furthest from the stainless-steel current collector interface denoted in green. In each of these PFIB cross section images the dark regions are lithium metal and the light regions left behind are the LiCa2 intermetallic. Electron diffraction from lamella produced from these cycled anodes shows that the calcium containing regions have not changed phase compared with that observed in the uncycled material.

Conclusion
This work acts as the first step towards producing an anode for all solid-state batteries that is resistant to failure during cycling due to loss of ionic and electronic pathways at the interface. The knowledge gained here will direct future anode development that will be the foundation of successful creation of a commercially viable all-solid-state battery for electric vehicles.

Tin Selenide (SnSe) has become a globally focused research topic in the field of thermoelectricity thanks to its low thermal conductivity and high electrical transport performance, which combined result in remarkable thermoelectric efficiencies. In its crystalline form, SnSe suffers from poor mechanical properties, rigid controlled crystal growth conditions and high production costs [1]. This has led the research to focus instead on SnSe polycrystals which, although less performing with respect to their crystalline counterpart, have great potential for significant efficiency enhancement [2]. A potential strategy to overcome the performance degradation, mainly related to the higher thermal conductivity of Tin oxide (SnOx) which percolates in the material through the grain boundaries, is by selective doping [3]. Here, we prove the effectiveness of Na doping in limiting the formation of SnOx and substituting the oxide at the grain boundaries in form of coherent precipitates through Scanning transmission Electron Microscopy (STEM). The ultralow spatial resolution imaging (~1Å) achieved with the aberration corrected STEM Spectra 300, combined with EDX spectroscopy, allows to map the elemental distribution at the grain boundary with atomic resolution, highlighting the presence of Na confined within the boundary.
The effect of the Na inclusions on the electronic and vibrational properties of SnSe polycrystals is further investigated through Low-Loss EEL Spectroscopy. Monochromated operation on the beam accelerated at 60kV, combined with low beam currents (~70pA) and convergence and collection semi-angles of 30 and 20 mrad, respectively, allow to collect the forward-scattered and higher momentum transfer signals in the first Brillouin Zone. From here, the information on the bandgap together with the plasmonic and phonon signals can be extracted for each probe position. In the specific, bandgap fitting across the doped grain boundary is supported by a customized Python algorithm [4], which highlights the decrease in the pure SnSe bandgap value due to the Na inclusions, in accordance with the DFT calculations. Further investigation on the vibrational signals within the low range of the EELS spectrum is performed to evidence the phonon modes that appear when in proximity of the grain boundaries. The specific vibrational-modes mapping will in the future enable the acquisition of phonon dispersion at grain boundaries, interfaces, edges, and various nature defects unlocking a powerful tool for thermoelectric performance evaluation at the atomic scale.

Background incl. aims
In contrast to perfectly periodic crystals, materials with short-range order produce diffraction patterns that contain both Bragg reflections and diffuse scattering. In this talk, we will show a quantitative comparison between three-dimensional electron diffraction (3D ED) and synchrotron single-crystal X-ray diffraction, both for the Bragg reflections and the diffuse scattering. The thermoelectric material Nb0.83CoSb was chosen as a reference material.
Methods
3D ED allows the study of nanometre-sized crystals, which are too small to be studied with single-crystal X-ray diffraction. The average structure (occupancies and atomic positions) was refined from the Bragg reflections, whereas the local structure (the vacancy distribution) was refined from the diffuse scattering. A model of the short-range order in Nb0.83CoSb was created by assuming that nearest and next-nearest neighbour vacancies avoid each other. The correlations between the first and next-nearest neighbour vacancies were refined using both a Monte Carlo refinement in DISCUS [1] and a three-dimensional difference pair distribution function (3D-ΔPDF) refinement in Yell [2].
Results
We found that diffuse scattering data used for quantitative analysis are best acquired in selected area electron diffraction (SAED) mode using an energy filter. Both the average and the local structure could successfully be refined from both the 3D ED and synchrotron single-crystal X-ray diffraction data acquired on Nb0.83CoSb. Fig. 1 shows that a good agreement was achieved between the simulated and the experimental intensity distribution of the diffuse scattering. The higher R-value for 3D ED compared to single-crystal X-ray diffraction is likely due to residual multiple scattering. The model of the short-range order in Nb0.83CoSb can easily be applied to determine the short-range order parameters in other materials with similar diffuse scattering, such as the lithium-ion battery cathode material LiNi0.5Sn0.3Co0.2O2.
Conclusion
The diffuse scattering in 3D ED data can be obtained with a quality comparable to that from single-crystal X-ray diffraction. Short-range order parameters could successfully be refined from the diffuse scattering in 3D ED data. As 3D ED requires much smaller crystal sizes than single-crystal X-ray diffraction, this allows to refine short-range order parameters in many technologically relevant materials for which no crystals large enough for single-crystal X-ray diffraction are available.

Poster Group 2

Background incl. aims
MXenes are a family of 2D transition metal carbide or nitride layers obtained from the exfoliation of nanolaminated ceramics called MAX phases [1]. Their chemical formula is Mn+1XnTz (n = 1, 2 or 3), with M a transition metal, X being C and/or N, and T are surface terminations (e.g. O(H), F, Cl) inherited from the exfoliation process. They present very good electrical conductivity, as well as high hydrophilicity, making them very promising materials for various applications, including transparent conductive electrodes or energy storage devices [2]. Our previous study [3] showed the strong influence of ion irradiation induced defects on the structural and physical properties of Ti3C2Tz MXenes, resulting in a reduced hydration potential, an increase in the charger carrier density as well as a modification of their optical properties. In the meanwhile, a large conductivity is preserved. Electron beams have also been shown to be a valuable tool for the structural engineering of MXenes on the nanometer scale [4]. Here, we present a new experimental protocol, which aims towards localized defect engineering in MXenes, using electron beam irradiation in situ in a transmission electron microscope (TEM), performed in cryogenic conditions.
Methods
This is achieved by adjusting the exposure time, the beam current and the number of frames in STEM-EELS (electron energy-loss spectroscopy) measurements, to reach an electron dose that allows for the introduction of defects into the sample. The study was performed on pristine Ti3C2Tz, exfoliated from its MAX phase precursors following the protocol detailed in [5], the powder was then dispersed in water to delaminate the MXenes sheets and dropped on a TEM lacey carbon grid. The TEM grid was placed on a cryo sample-holder and measurements were performed at liquid nitrogen temperature.
Results
At low temperature, irradiation conditions can be controlled precisely, by the creation of either punctual depressions, roughly the size of the electron beam, or bigger “crater-like” dips spanning over hundreds of nm² (Figure), depending on the irradiation conditions. The evolution of the structure and chemistry of the sample is monitored as a function of the electron dose using core-loss spectra acquired both during and after irradiation.
Conclusion
This study gives a valuable insight into the defect formation mechanisms at play in electron beam irradiation of MXenes, by observing the behavior of the surface functional groups, as well as the core atoms in regards to the incoming high-energy electrons. This innovative approach can potentially be generalized to other MXenes and 2D materials, as well as up scaled to thin films using other electron irradiation techniques such as SEM.

Poster Group 2

Background
Zirconium (Zr)-based alloys, serving as cladding materials for nuclear reactor fuel, are susceptible to oxidation under harsh operation conditions. The stress redistribution and strain anisotropy induced by oxidation could elevate the risk of reactor failure and limit the operational economy. Efficient in situ strain mapping techniques are crucial for elucidating the fundamental mechanisms of oxidation processes and advancing the development of more sustainable cladding materials to ensure the safety of nuclear reactor operations. Recent developments of MEMS-based NanoReactors enable in situ TEM studies of reactions at temperatures up to 1000 °C and pressures up to 2 bar. The integration of a vaporizer extends in situ gas phase TEM from dry to humidified gas environments. Specifically, for Zr-based alloys, these innovations facilitate oxidation studies under both dry oxygen and water vapor conditions.
In this work, we pioneer an in situ strain mapping methodology to explore oxidation processes in zirconium by integrating four-dimensional scanning transmission electron microscopy (4D-STEM), MEMS gas-cell holder, precession electron microscopy (PED), and direct electron detector (DED). Central to our successful strain mapping is achieving optimal signal-to-noise ratio within nanobeam electron diffraction patterns (NBEDs).
Methods
A DENSsolutions' in situ gas phase TEM system Climate G+ and a FEI Tecnai 20 with NanoMEGAS ASTAR and Topspin platform were used in this work. The Zr sample was first cut and thinned by the focused ion beam (FIB) and then transferred to the Climate nano-reactor.
Results
Figure 1 depicts the influence of precession on a representative nanobeam electron diffraction (NBED) pattern, an area strain mapping, and an area orientation mapping by toggling precession off and on over the identical region on the Zr sample. The application of precession visibly reduces their sensitivity to the sample thickness and its local bending, increases the number of higher-order reflections, and improves the signal-to-noise ratio. Therefore, it enhances the straining mapping precision and orientation reliability.
A comparison between in situ gas-cell 4D-STEM mapping results using PED at Argon gas pressures of 0 mbar and 500 mbar tells although both PED patterns retain similarity to kinematic ones, the increased pressure lowers the signal-to-noise ratio. Consequently, the reliability of the strain mapping at higher pressure is reduced, as marked by the additional noise present in the strain mapping.
Further details on how we tackle the challenges of FIB sample preparation on a gas cell, the conflict of sample evolution process in a few seconds and SPED data acquisition in a few minutes and so on will be presented on site.

Conclusion
Our approach facilitates precise, nanometer-scale strain mapping across a large field of view during zirconium oxidation. This developed workflow has significant implications for corrosion studies, offering profound insights into the chemo-mechanical evolutions in materials subject to harsh environments.

Poster Group 2

Background incl. aims
Cryo electron microscopy (Cryo-EM) single particle analysis (SPA) has become a major structural biology technique in recent years. High-resolution cryo-EM structures typically require higher voltage cryo-TEMs with coherent FEG sources, stable columns, autoloader systems and direct electron detectors. These setups are specialised for Cryo-EM work and expensive to establish and maintain. More recently the concept of using 100keV cryo-TEMs has been introduced as a way to make cryoEM more affordable and hence accessible to a larger group of researchers. However, so far, the implementation of these 100keV have relied on specialised cryo-TEMs with FEG sources and better and more stable optics than usually present in common 120keV TEMs.

Methods
We here explored whether a standard 120keV TEM, commonly available at many places worldwide, can be upgraded with a direct electron detector and used for higher resolution cryo-EM. Our setup consisted of a TFS Tecnai Spirit G2 with lanthanum hexaboride (LaB6) thermionic electron emitter and with a Gatan 626 cryo-transfer holder. The microscope was upgraded with a Gatan Alpine direct detection camera optimised for 100 to 200keV. Automated data collection was set up using Serial EM.

Results
Using this imaging configuration, we were successful in achieving a 2.7Å reconstruction for the cryo-EM standard apoferritin. We were also able to resolve a more challenging small 64kDa protein haemoglobin to 4.5Å. Furthermore, we solved an asymmetric membrane protein, 160kDa GPCR (M4 muscarinic acid receptor) to a resolution of 4.5Å. Importantly, all the results were achieved using limited datasets ranging from 700-1500 movies, making it feasible to collect these datasets with a side entry cryo-holder.

Conclusion
These results showcase a potentially widely accessible microscope configuration to obtaining interpretable cryo-EM structures. However, we suggest that the true value of using standard 120keV TEMs is in the potential for many EM facilities and laboratories to setup high quality cryo-EM SPA sample screening without the need to procure specialised Cryo-TEMs. This could hence help to considerably lower the entry barrier for cryo-EM SPA and contribute to the “democratisation” of Cryo-EM.

Poster Group 2

Background incl. aims
The conversion efficiencies of single-junction solar cells have reached values very close to the theoretical Schockley-Queisser limit (~33%). One strategy for exceeding this value is to use tandem solar cells [1] combining a top cell optimized to absorb solar radiation in the UV/visible range with a bottom cell optimized for IR absorption. As part of the ANR EPCIS project [2], we have developed this type of cell using a Cu(In,Ga)S2 (CIGS) layer (with a band gap of 1.65-1.70 eV) deposited at low cost by co-evaporation on a Si substrate (band gap of 1.1 eV). However, the adhesion of a CIGS layer to Si is very poor, so an intermediate layer is needed to improve adhesion. The GaP material was chosen for 3 main reasons : 1) its cubic symmetry with a lattice parameter close to that of Si and also to that of CIGS, for a GGI close to 20% (chalcopyrite material with pseudo-cubic quadratic symmetry with c~2a) can promote epitaxy growth of the CIGS film, 2) such layer can act as a diffusion barrier to prevent diffusion of species between layers during the growth process, and 3) its low absorption coefficient (2.26 eV indirect bandgap) coupled with an electron affinity around 3.8 eV make it an ideal selective contact for holes. Despite the above-mentioned advantages, electrical performances of our synthesized tandem solar cells are still very low. We combined different characterization techniques including S/TEM to try understanding the relation between microstructure and optoelectonic performances.

Methods
Growth parameters including temperature, GGI=[Ga]/([Ga]+[In]) and CGI=[Cu]/([Ga]+[In]) can be adjusted during the co-evaporation process to deposit the CIGS layer on the GaP/Si substrate. When CGI is greater (less) than 1, the film is described as "Cu-rich" ("Cu-poor"). Various S/TEM techniques (ACOM-TEM, probe-corrected S/TEM imaging, spectroscopies) were used to study the 'Cu-rich' and 'Cu-poor' CIGS films: the epitaxial growth of the chalcopyrite CIGS layer, the presence of other crystalline phases and their orientation, and the identification of certain intragranular defects. The interdiffusion of elements and the possible presence of an additional layer between the CIGS and the GaP were characterised by atom probe tomography (APT).

Results
In the Cu-poor sample, the existence of a CuIn5S8 thiospinelle phase (TS) was demonstrated in addition to the CIGS chalcopyrite phase (CH) with this epitaxial relationship: CH[100](001)//TS[100](001)//GaP[100](001)//Si[100](001). In the case of Cu-rich sample, the epitaxial relationship is the same, except that there is no TS phase (Figure). However, the interface between GaP and CIGS layer is much more abrupt in the Cu-poor case than in the Cu-rich case where a few nanometers thick layer made of Cu and P is detected.

Despite the presence of TS phase and interface layers, the desired chalcopyrite phase is the most present. Unexplained contrast in HAADF-STEM images for both kind of samples led us to consider defects such as cation antiphase boundaries. On the basis of these contrasts, three types of CAPB were conceptualized.

Conclusion
Combined with other more macroscopic techniques, S/TEM and APT have enabled us to show that the growth of a CIGS layer on a GaP/Si pseudo-substrate for the application of tandem solar cells is far from ideal. Differences in Cu stoichiometry in the CIGS film were also highlighted.

IM-05 (2), Lecture Theater 3, august 26, 2024, 14:00 - 16:00

Background
Thermodynamic properties such as heat capacity or thermal conductivity depend critically on phonon dispersion. Determining these properties from nanometer sized regions would enable significant advances in nanoscience. Measuring phonon dispersions in the electron microscope with spatial resolution of a few nm was demonstrated in 2016 [1] and later optimized for parallel acquisition [2-3]. We have now extended this technique to sample two momentum directions, thus obtaining phonon dispersion surfaces in 3D momentum-energy space. To study the influence of Umklapp scattering (scattering into higher Brillouin zones) and dynamical diffraction on the measured dispersion, we compare experimental results to electron-phonon scattering simulations that include dynamical diffraction.

Methods
A FIB lamella from diamond in the [110] zone axis was cut from a single crystal and polished to about 80 nm thickness. We used a Nion HERMES microscope operated at 80 kV with a convergence semi-angle of 1.6 mrad and equipped with a Dectris ELA direct detector to acquire phonon dispersions in parallel acquisition mode utilizing a slot as the EELS entrance aperture to define a line in momentum space. The diffraction pattern was consecutively displaced over the slot aperture by 4.1 mrad per step with a slot width of 6.6 mrad to obtain individual slices of 3D energy-momentum space. The data from each position was post-processed by registration and integration of the 120 frames of 1 s acquisition time (26 min total acquisition time for the 13 positions). The zero-loss lines were straightened and other processing steps applied before stacking the slices in 3D to reconstruct the diffraction plane. The data was then visualized using tomviz [4].
To simulate electron scattering from the diamond sample including phonon scattering and dynamical diffraction, a Bloch wave-based method developed by Rez and Singh was used [5]. This method applies operators for dynamical diffraction, phonon scattering followed by further dynamical diffraction to evaluate the phonon scattered intensity. The experimentally determined sample thickness of 76 nm was used in the calculations.

Results
Fig. 1a shows the phonon dispersion from diamond spanning multiple Brillouin zones. While the diffraction intensities fade quickly with increasing scattering angle, the phonon branches first become more intense and then decrease only slowly. This clearly demonstrates that Umklapp scattering dominates the interaction between the fast beam electrons and phonons in the sample. Fig. 1b shows the experimental phonon dispersion surfaces and the results from the calculation are given in Fig. 1c. We will quantitatively compare the experimental and calculated results. We also

investigate the influence of high-angle phonon scattering, which should be a multi-phonon process known as thermal diffuse scattering, by comparing experiment with calculations for large scattering angles.

Conclusion
We have demonstrated the experimental reconstruction of phonon dispersion surfaces in momentum-momentum-energy space using electron microscopy. The comparison of such rich data sets with Bloch wave-based electron-phonon scattering simulations that include dynamical diffraction makes it possible to understand the fundamental processes of electron-phonon interactions. This paves the way to obtain quantitative phonon densities of state at nanometric spatial resolution, which can be used to determine thermodynamic properties such as heat capacity or thermal conductivity.

Influential factors affecting the quantification accuracy of magnetic moments with electron magnetic chiral dichroism technique

Dr Xiaoxiao Fu[1], Mr Zhixin Zeng[1], Miss Qiwen Hu[1], Dr Xiaoxu Huang[1]
[1]International Joint Laboratory for Light Alloys (MOE), College of Materials Science and Engineering, Chongqing University, Chongqing , China

Poster Group 2

Background:
Electron magnetic chiral dichroism (EMCD), a transmission electron microscopy (TEM) technique based on electron energy-loss spectroscopy (EELS), allows quantitative measurements of element-selective spin and orbital moments at a high spatial resolution [1-2]. Since EMCD was first demonstrated in 2006 [1], the investigation of the influencing factors of quantitative determination has always been fundamentally important. The influencing factors of asymmetrical diffraction condition, plural scattering effect and signal-to-noise ratio (SNR) have been mostly discussed in the literature, and some data treatment methods have been correspondingly proposed. However, more questions are open. First, deconvolution has been routinely applied to EMCD spectrum to remove the plural scattering, but how effective the deconvolution of momentum-resolved spectra can be? Second, how the universal problem of electron damage can affect the EMCD quantification? Third, what is relationship between SNR and quantification accuracy? We explored our answers to these questions.

Method:
For the first question, TEM experiments were performed on a wedge-shaped area in a plane-view TEM specimen of Fe/MgO(001) thin film. A series of low-loss EELS, conventional in-axis core-loss EELS with Fe-L2,3, and pairs of q-resolved core-loss EELS with Fe-L2,3 edges at two chiral positions were acquired from areas of different thicknesses, using spectrum imaging in the scanning TEM mode (STEM-SI), as in Figure (a). The in-axis EELS and q-EELS before and after deconvolution with changing thickness were then compared.
For the second question, TEM experiments were performed on a cross-sectional TEM specimen of Co/MgO(001) thin film. The surface oxidation layer and amorphous layer were damaged under continuous electron irradiation, as in Figure (a). The changes in shape and intensity of EELS spectrum Co-L2,3 edges under continuous electron irradiation were followed and its influence on the shape of EMCD spectrum was discussed.
For the third question, a pair of EELS spectra at Co-L2,3 edges were mathematically constructed. The background, L3 edge, L2 edge and continuum background of each spectrum were respectively described by one inverse power exponent function, two gaussian functions and one double arctan step function. Various degrees of white gaussian noise were added to the EELS spectra. EMCD spectra with different SNR were thus obtained, and quantification results were compared.

Results and Conclusions:
(1)The q-resolved spectra after deconvolution still contain residual plural scattering, which is more significant in thicker areas than thinner ones, as shown in Figure (c-d). It is then derived that the existence of such residual plural scattering would bring artifacts to ml/ms value. The thicker the detected area is, the higher the ml/ms value would be obtained even after deconvolution. We suggest that even deconvolution would be performed, EMCD spectra should be acquired from

sufficiently thin samples for minimizing the plural scattering effect in originally detected spectra before any deconvolution [3-4].
(2) Under sustained electron irradiation during spectra acquisition, a gradual removal of the thin surface oxidation layer, rather than a simple continuous thickness reduction that changes the diffraction and plural scattering conditions, can lead to notable residual nonmagnetic components in EMCD spectra and may make the quantified result of the orbital-to-spin moment ratio remarkably higher than the actual value, as in Figure (f-g). It was thus proposed to pay great attentions to the surface oxidation and to minimize the effect of oxidation layer by performing electron irradiation on the target area prior to EMCD experiments, for improving the quantification accuracy [5].
(3) For quantitative measurement of orbital-to-spin moment ratio of Fe, Co, Ni with an error range within about 50% of actual value, the minimum noise degree should be smaller than 0.01.

Structure, Chemistry, and Interface of Dispersoids in Powder Metallurgically Processed Ni based 617 ODS Alloy

Chanchal Ghosh[1,3], Dr. Arup Dasgupta[1,3], Dr. Sudip Kumar Sarkar[2], Dr. Deodatta Shinde[2,3], Dr. R Mythili[1,3], Dr. Aniruddha Biswas[2,3]

PS-02 (3), Lecture Theater 4, august 30, 2024, 14:00 - 16:00

Background incl. aims:
Ni base Alloy 617 super alloy is well-known to the metallurgists and materials scientists owing to solid solution strengthening aided with precipitation strengthening with the formation Ni3(Al,Ti) type γ' precipitates. Interestingly, this alloy system does not undergo any phase transformation upto its melting point and has impressive high temperature strength and oxidation resistance upto about ~ 1000 °C making this alloy system quite attractive for structural applications at elevated temperatures. However, the Ni3(Al,Ti) type γ' precipitates dissolve in the matrix from about 700 °C following which, carbides provides the strength to this alloy system. In order to retain the strength of Alloy 617 upto 1050 °C while maintaining its oxidation resistance properties, this alloy has been conceptualized and developed by powder metallurgical route using fine yttria as (~ 0.6 wt%) dispersoid [1]. During the high temperature processing of the material, yttria undergoes solid-state reactions with different alloying elements present in the matrix and form different kinds of dispersoids/ precipitates (terminology maybe debated). Detailed electron-microscopy characterizations including High Angle Annular Dark Field (HAADF) analysis in a probe aberration corrected scanning TEM of the solid state reacted dispersoids/precipitates shows different contrast [2]. STEM-HAADF, being a Z^2 dependent technique, the contrast difference of the dispersoids is directly related to the composition of the dispersoids. Most exciting finding of the present work is the formation of a bi-phase precipitates resembling as Janus particle comprising Y-Al-O and Al-O. Detailed correlative microscopy analysis including probe aberration corrected differential phase contrast imaging (STEM-iDPC), STEM based tomography and 3D-Atom Probe Tomography (APT) have brought out details about their chemical composition, structure, and a possible mechanism of formation of these bi-phase Janus particles. The studies have also fascinatingly revealed natural methods of the system to minimize interface strain through formation of core-shell structures in some cases.
Methods:
Alloy 617 ODS alloys have been developed by powder metallurgical route. The Alloy was prepared by ball milling water atomized powders of Alloy 617 and 0.6 wt. % of nanocrystalline bcc-Y2O3 followed by consolidation in SPS. Corelative microscopy including ultrahigh-resolution Cs-aberration-corrected scanning transmission electron microscopy (STEM) based techniques and 3D atom probe tomography have been used to resolve the structure, chemistry, and interfaces of the nano-dispersoids in this alloy.
Results:
STEM-HAADF analysis of the complex nano-oxides shows a variety of contrasts, namely, bright, dark, and bi-phases. STEM-XEDS and STEM-EELS demonstrates the differences in chemical composition of these particles. Most intriguing aspect of the study is the discovery of bi-phase Janus particles. Interestingly, the bi-phase contrast of the Janus particle consists both the heavy and light atoms together. One phase of the Janus particle has been identified as Y-Al-O complex oxide, whereas the

other phase mainly comprises relatively light Al-O. In overcoming the limitation of conventional STEM-HAADF imaging, the integrated differential phase-contrast imaging technique was employed to investigate the oxygen atoms along with other elements in the yttrium rich dispersoids and its interface with the matrix. Detailed atomic resolution information of both phases has been analyzed using STEM-iDPC technique. For the monoclinic Y-Al-O complex oxide structure a few atoms thick Al-O interlayer (shell) around a monoclinic Y–Al–O core in the Ni-matrix. On the other hand, when the dispersoid is a hexagonal type Y–Al–O complex, the interface energy is already low; maintaining a semi-coherent interface and it was devoid of a shell. STEM based tomography analysis has explicitly revealed the shape of the Janus particles, where a 'cup shaped' Al-O surround the 'cone shaped' Y-Al-O complex oxides as shown as inset in Fig. 1. Interestingly, APT analysis confirms the presence of two different types of Janus particles in the system with two different morphologies, (i) cup shaped Al-O phase surround Y-Al-O complex oxide and (ii) cup shaped Y-Al-O surround the Al-O. However, APT analysis shows that for the later type of the Janus particle, core is Al-O rich and the shell is also Al-O rich but contains 3–5 at. % of Y. Direct structure imaging of the interfaces between Y-Al-O/ Al-O and Al-O/ Ni based matrix of the Janus particles have been carried out, where detailed STEM-HAADF and iDPC analysis of the interface between Al-O/ Ni based matrix indicate the periodic disappearance of atom columns from Al-O phase (Fig. 1). Understanding of this phenomenon is quite intriguing and can be explained in terms of vacancy ordering along Al-O/ Ni matrix interface. Quantitative analysis including STEM-HAADF simulation and microstructure modelling towards understanding mechanism of the formation of Janus particle and particularly interface structure is in progress.

Conclusion:

Bi-phase Janus particle is produced as a solid solution product during the processing of alloy 617 ODS alloy during powder metallurgical route. The Janus particles are stabilized in a 'cup-cone' shaped morphology, where both the phases are compositionally stabilised as Y-Al-O complex oxide and Al-O oxide or vice versa. Formation of vacancy ordering has been observed at the interface between Al-O bi-phase and matrix, which is a natural method adopted by the material to minimize the misfit strain across the interface.

Mitigating radiation damage in beam sensitive battery materials by adapting scanning parameters

Mme. Hannah Nickles Jäkel[1], Mr Eric Gautron[1], Mr Maurice Peeman[2], Mr Philippe Moreau[1], Ms Patricia Abellan[1]
[1]Nantes Université, CNRS, Institut des Matériaux de Nantes Jean Rouxel, IMN, 44000 Nantes, France, [2]Thermo Fisher Scientific, Eindhoven, Netherlands

PS-04 (4), Plenary, august 27, 2024, 14:00 - 16:00

Background incl. aims
Electron-beam sensitivity of battery materials hinders the full potential of high-resolution STEM-EELS insights on battery failure mechanisms. It is therefore important to understand how electron beam induced alterations can be minimized. Beam damage mitigation in STEM can be achieved by adjusting electron probe properties such as beam size, current and acceleration voltage, by changing dwell time, but also by changing the scan pattern and thus, exploiting the spatial component of beam damage (1). For the latter, many different approaches have shown great promise. Alternative scanning techniques, such as leapfrog scanning, which explores the effect of increasing pixel spacing (2), or sparse scanning, which irradiates only a percentage of pixels (3), can reduce damage compared to conventional raster scanning. Since beam damage is a process that is highly dependent on the type of material being irradiated, damage mitigation techniques require material-specific investigations to ensure effective adaption of the scanning parameters. Here we are interested in Li-containing battery materials, where for LiF, for example, radiolysis is more dominant than knock-on damage (4). Methodical experiments are necessary to understand how irradiation conditions like acceleration voltage, electron dose, and scan pattern can be optimized for specific electron beam sensitive battery materials.
Methods
In order to determine the optimum acceleration voltage, damage cross-sections for different acceleration voltages are calculated for various battery materials. To gain a better understanding of the damage mechanisms involved, damage is systematically induced on Li-containing battery materials and monitored with STEM-EELS ((S)TEM Themis Z 3G). The effect on materials damage of conventional scan patterns is compared to different “alternative” scan patterns.
Results
The calculated damage cross-sections show, that avoiding knock-on damage by imaging below a threshold voltage is not applicable for (S)TEM measurements of lithium-containing battery materials. STEM-EELS observations provide insights on the degradation of LiF to metallic Li, being consistent with radiolysis being the dominant damage mechanism. EELS spectra of LiF over radiation time show that the LiF bulk plasmon peak and the Li K-edge for LiF at 61 eV decrease, while the bulk plasmon peak for metallic Li appears at 7 eV. Lastly, scanning variations give insights on damage delocalization in battery materials. Damage imposed by conventional scanning is compared to different alternative scan patterns, by quantifying electron beam induced alterations in image intensity.
Conclusion
With the gained understanding for radiation damage in specific battery materials, optimized acceleration Voltage and scan pattern can be chosen to reduce electron beam induced alterations. Optimized scanning parameters enable higher imaging flexibility and could provide new insights into battery failure mechanisms.(5)

Poster Group 2

Background incl. aims
It is a common practice to correlate multiple imaging techniques to achieve a comprehensive understanding of the interplay between material structure and function. Beyond the geometric structure, the chemical composition, particularly at the nanometer scale, plays an essential role. However, there is a shortage of instruments capable of imaging light-mass elements with sufficiently high spatial resolution and sensitivity. This gap is addressed by TOFWERK's fibTOF platform, offering high spatial resolution and 3D chemical imaging of all the elements of the periodic table, including light-mass elements. This capability is demonstrated through the application examples below, which are taken from the battery and metallurgy sectors.
Methods
fibTOF is a Secondary Ion Mass Spectrometry (SIMS) detector designed to be attached to a Focused Ion Beam (FIB) Scanning Electron Microscope (SEM). fibTOF extends microscopic analysis to probe the chemical composition of solids at the nanometer scale with sensitivities down to the ppm range. The properties of a FIB as a primary ion source to erode and ionize material is used. For each pixel probed by the FIB, the released secondary ions are extracted and characterized. The combination of the mass spectra/pixel, results in an intensity map of elements for a mass range of 0-500 Th. As the FIB repeatedly scans the region of interest (ROI), a 3D data set is generated.
Results
The value of the fibTOF is demonstrated by the investigation of a Solid-Electrolyte Interface (SEI) composition at the anode after galvanostatic cycling. We explore how various molecular additives affect its stability.
Lithium ions have been observed at various penetration depths, indicating differences in SEI formation efficacy based on the additives used. The lower SEI formation efficiency explains the diminished battery performance due to ongoing electrolyte degradation. In addition, measurements of Mn and Ni on the anode corroborate irreversible phase changes and metal dissolution of the cathode.
The use of the fibTOF has been shown as well in correlation with hardness tests done by nanoindentation of an M3 high-speed steel alloy. Certain regions of the sample, chemically characterized as hard phases, exhibited soft mechanical properties. These regions also showed the presence of hydrogen, hinting at a potential link to hydrogen embrittlement. Notably, both case studies were carried out using elevated sputtering and detection rate of the fibTOF.
Conclusions
The studies presented demonstrate fibTOF's efficacy in light-mass element imaging, showcasing its versatility and reliability in analyzing diverse materials and complex microstructures. Furthermore, the demonstrated capability of fibTOF to manage enhanced signals bolsters its potential for a broad spectrum of applications.

Poster Group 2

Background incl. aims
The semiconductor industry is continuously working on improving the performance of modern electronics and new components development. Key physical parameters like dopant concentration levels, carrier types, and crystalline defect densities are fundamental factors that influence the electrical performance of semiconductor devices. To improve device performance, novel methodologies, instrumentation, and workflows are being developed. The key requirement is the ability to investigate samples with nanoscale features to characterize device reliability or failure root cause. One example of a progressive approach for characterizing complex physical and electrical properties of semiconductor materials is correlative in-situ microscopy. A combination of different imaging systems provides a comprehensive understanding of the sample properties without the need to move the sample between multiple instruments.
Methods
The AFM-in-SEM approach, combining Atomic Force Microscopy (AFM)-based techniques with Scanning Electron Microscopy (SEM)-based or Focused Ion Beam (FIB)/SEM-based techniques, provides means to integrated correlative approach for studying semiconductor materials and devices. This solution allows for non-destructive mapping of diverse electrical properties of trenches, measuring gate dimensions, or localizing defects, which could help to understand the device processes. This approach provides the advantages of combining the benefits of capabilities of site-specific sample preparation by FIB, and ultra-high resolution imaging by SEM and AFM techniques. This integration helps in revealing the structures below the sample surface and measuring various properties at the exact location under in-situ conditions. Additionally, it provides quantitative 3D information while avoiding sample or environmental changes such as differential pressure or sample contamination.
Using the AFM module LiteScope, integrated inside the FIB/SEM, it is possible to measure high-resolution topography, and various electrical properties using techniques such as Conductive Atomic Force Microscopy (C-AFM), Scanning Spreading Resistance Microscopy (SSRM) and Kelvin Probe Force Microscopy (KPFM). C-AFM enables electrical conductivity measurement with nanoscale resolution, while SSRM can provide valuable information on dopant concentration profiles in semiconductors. KPFM is a non-destructive technique that measures surface potential, giving insight into electronic properties.
Results
With such an instrumentation, the samples are either in-situ lifted-out, or bulk x-sectioned. First we calibrated the probe measuring SSRM resistance on p- and n-doped silicon substrate, reference samples for dopant concentration measurement in SEM. Then, we analyzed MOSFET high power transistor by SSRM, showing the resistance of different components of the sample, see Fig. 1. The resistance can then be calculated to the dopant concentrations, using the calibration data from reference samples. This workflow proves that the dopant concentration steps of transistors can be

safely measured under in-situ conditions in SEM, thus, enabling quality control and failure analysis of semiconductor components.

Conclusion

In summary, integrated AFM-in-FIB/SEM is a valuable instrumental combination for studying semiconductor materials or devices in order to improve device performance and enhance failure analysis success.

LS-04 (1), Lecture Theater 4, august 29, 2024, 10:30 - 12:30

Background incl. aims
In case of a damage to the anterior cruciate ligament (ACL), a detailed identification of its morphological structure is essential for the biomechanically valid reconstruction of the ligament [1]. However, so far, most anatomical studies on the ACL were based on macroscopic evaluations [2] or low-resolution clinical imaging technologies (e.g. clinical computed tomography – CT, magnetic resonance imaging – MRI) [3,4]. The objective of this study was to investigate the 3D morphology of ACL in anatomical flexion and extension positions, focusing on the arrangement of its anterior and posterior fiber bundles and its femoral and tibial bone attachments. This was achieved through the correlative imaging by micro-CT, a non-destructive high resolution 3D imaging technique, and histology, leading to the identification of the four layers insertion zone of the ligament.

Methods
Healthy human knee samples (n = 2) were chemically fixed in formalin solution in knee flexion and extension and dehydrated by soaking the specimens in solutions of ascending ethanol concentration and in hexamethyldisilazane. Micro-CT analyses were carried out using an EasyTom XL Ultra 230–160 micro/nano-CT scanner (RX Solutions, Chavanod, France) with a voxel size of 17.5 µm. The generated CT datasets were analysed to create 3D models of both knees in flexion and extension using CTAn and CTVox softwares. After the micro-CT analysis, both knees were rehydrated in solutions of descending ethanol concentration, washed in distilled water, and decalcified with an aqueous solution composed of formic and nitric acid. The micro-CT 3D models were used as references to guide the orientation of the tissue for the histological analysis. Histological 5 µm thick sections were stained with hematoxylin and eosin (H&E) and Safranin O and registered, using Dataviewer software (Bruker micro-CT, Kontich, Belgium), with the corresponding orthogonal micro-CT sections.

Results
The micro-CT imaging analysis permitted the morphological 3D visualization of both soft and hard tissues of the knee in extension and flexion. These anatomical knee components were digitally identified for subsequent 3D modelling analysis, which showed a differential orientation of the ACL bundles when the knee was flexed. In particular, in the extended position the ligament exhibited a parallel course of the bundles, whereas when the knee was flexed a twisting of the bundles disrupted the parallel orientation. Direct comparison with histology permitted to identify the ACL insertion structure, comprised of four layers: ligament, fibrocartilage, mineralized fibrocartilage and bone. Moreover, this versatile method can be applied to define important joint structures, including blood vessels and nerves.

Conclusion

This study underlined the efficacy of micro-CT method to visualize the intricate anatomy of the ACL. Our protocol enabled correlative imaging using micro-CT and histology, allowing the precise assessment of ACL shape and positioning within the knee joint across different extension and flexion states. A detailed 3D description of ACL anatomy can pave the way for new regenerative medicine and tissue engineering approaches with the aim of improving diagnostics and treatment strategies for ACL-related knee pathologies.

Poster Group 1

Background incl. aims
The disruption of normal intervertebral disk (IVD) structure and its subsequent degeneration significantly contributes to the onset of low back pain [1]. To date, the human IVD 3D microstructure characterization has been confined to imaging the annulus fibrosus (AF) [2] and the subchondral endplate [3]. Our study aimed to propose a step-wise approach for the complete morphological investigation of human IVDs at various tissue processing stages using a non-destructive micro-CT analysis. This approach allowed detailed 3D visualization of distinct IVD anatomical components: nucleus pulposus (NP), AF, and the orientation of collagen fibers. Additionally, the method provided a precise quantification of lesions and calcifications within the disk, which affect the integrity of its microstructure and thus its functional and biomechanical characteristics [4].

Methods
The IVDs (n = 14) were examined through the use of the micro-CT EasyTom XL Ultra 230–160 micro/nano-CT scanner (RX Solutions, Chavanod, France) with a voxel size of 40 µm. Each sample was scanned label-free (both frozen and thawed) and after formalin fixation and staining of the tissue in an iodine-based contrast agent solution. The calcifications and lesions present in the tissue were determined with an automatic segmentation approach using the software Avizo (Thermo Fisher Scientific, MA, USA). For each processing stage, the calcification and lesion volume fractions were compared considering the entire disc and selecting the AF region. In addition, the degree of contrast enhancement has been defined calculating the Hounsfield Units (HU) relative to the acquired CT values.

Results
Thawed samples allowed an accurate quantitative analysis of lesions and calcifications present in the native IVD. Additionally, the analysis of frozen samples provided valuable insight into the alternate laminal pattern of the AF. Iodine staining, while providing a homogeneous increase in contrast and simultaneous visualization of the IVD anatomical components, was time-consuming (2 weeks of staining) and resulted in the extrusion of the NP, leading to an increase in lesion volume fraction. The contrast measured in HU increased between the different preparation steps.

Conclusion
The examination of frozen, thawed, and chemically fixed-stained IVD tissues using micro-CT revealed distinctive microstructural information, presenting different benefits for each stage. The systematic methodology used in this study had the aim to define the trade-off between contrast enhancement and processing artefacts. A label free imaging of the IVD represents a valuable option for a 3D

morphological investigation of the sample, especially when combined with biomechanical testing due to its non-destructiveness thus preserving the original stiffness and geometry.

IM-13 (2), Lecture Theater 5, august 27, 2024, 14:00 - 16:00

Background incl. aims
It is increasingly important to understand the 3D ultrastructure of cells and tissues particularly in the study of diseases and infection. The study of infection requires a complete understanding of where the virus, parasite or pathogen is located within the cell, how it interferes with the host cell's mechanisms and to follow its development. Several types of imaging are extremely powerful techniques in the study of these processes: XRFM & PC imaging/tomography, XAS & cryoEM/ET. Each of these techniques produces unique information that is crucial in the overall understanding of the problem. However, each technique requires different sample preparation (e.g. ice protective layer thickness) & different supports and holders, which makes it extremely difficult to locate and study the same area of interest in each sample in diverse imaging modalities.

Methods & Results
A complete experimental setup (Fig. 1) accompanied by an efficient workflow, to reach an optimised preparation process allows the easy transfer of the sample from one technique to another. New supports and sample holders are being designed and developed to be compatible with diverse targeted cryo-imaging techniques on near-native state frozen-hydrated samples (Fig. 2). EasyGrid machine [1] is used to automate and validate the sample vitrification. The preliminary results on the dose show that the radiation damage is very limited, suggesting that we can study the same sample by EM after having targeted a region of interest (bio-elemental accumulation/targeted organelles) with XR imaging. The optimization of the sample vitrification with a better amorphous ice quality and a reduction of crystallin ice, ice cracks and a better control of the ice thickness seem to allow a reduction of the flux used for the same image quality. For a multimodal and multiscale sample analysis, a new multimodal imaging pipeline is currently in development with the new design of sample support (collaboration with Silson company) compatible with the above-mentioned imaging and sample preparation instruments. It will allow the study of the same region of the same sample across many scales and tracking down the full process of biochemical mechanisms.

Conclusion
The generation of a new cryo-sample preparation process, suitable for XRFM, PC and Cryo-EM techniques, will make the beamtime (synchrotron/EM) use more efficient, potentially improving the success rate of multimodal imaging projects that will benefit a wide user community. The target community is the historical X-ray imaging users in biological fields who need to overcome difficulties in certain challenging projects, and a rapidly growing new population of users: the non-experts who will benefit directly from a complete multimodal imaging pipeline.

Poster Group 2

Breakthroughs in transmission electron microscopy (TEM) have opened for visualizing nanomaterials with atomic resolution and uncovering the surface terminations that are governing e.g. catalytic properties. In a TEM experiment, the most informative outcome is the recovery of the electron wave function exiting the nanomaterial. While different experimental and mathematical reconstruction schemes exist to recover the underlying exit wave, the transformation of exit waves into a three-dimensional (3D) structural model is still being debated. Recently, our group presented an analytical model to describe the 3D atomic-scale arrangement in an excited 2-dimensional Co-Mo-S nanocrystal [1]. The model was based on channeling theory and made for the first time use of the full shapes of the atomic columns in the exit wave. Extending this model to an arbitrary 3D nanomaterial is challenged by the role of extinction distance in relation to the sample thickness as well as the irregular surface both at entrance and exit of the nanomaterial. Here, we will outline the development of this analytical approach to investigate arbitrary nanomaterials at 3D atomic-resolution.

We examine nanometer-sized metal nanoparticles with a focus on their terminating surface structure. The exit waves are reconstructed from experimental focal series of bright-field TEM images, which carries most signal pr. electron. This is vital for investigating surfaces of nanomaterials since under coordinated atoms at the surface are particularly prone to beam-induced alteration compared to the bulk. Imaging is therefore done with low electron dose rates using direct electron detectors (DED) to establish sufficient SNR for the reconstruction while maintaining the pristine structure of the material.

With the complex exit wave, we use the channeling approaches in [1,2] to determine the 3D atomic position and stoichiometry of atomic columns of a carbon supported Pt nanoparticle with a diameter of 5 nm. We present a strategy to counteract the influence of extinction and show how this drastically reduces the elongation of the 3D tomogram along the beam direction. Furthermore, we also present a strategy for the non-uniform entrance and exit surface of the nanoparticles.

In this work, we present an approach to reconstruct 3D structural information about nanoparticles from electron wave functions exiting the sample. Based on channeling theory, an analytical model is outlined to establish the location and stoichiometry of the atomic columns and approaches to counterbalance the role of extinction and irregular entrance and exit plane surfaces are

demonstrated. The present work therefore build a foundation to recover a 3D atomic model of a nanoparticle and thereby uncover its exposed surface structure. The present approach should be generally applicable to any nanomaterial even under exposure to reactive environments and should thus aid the understanding of gas-surface interaction is diverse fields such as crystal growth, corrosion, and catalysis.

Novel combination of integrated FLM with cryo-FIB allows targeted cryo-ET sample preparation from challenging samples

Marit Smeets[2], Samuel Zachej[1], Wessel Teunisse[2], Jakub Javůrek[1], Dominik Pinkas[3], Vlada Filimonenko[3]

IM-11 (2), Lecture Theater 5, august 30, 2024, 10:30 - 12:30

Cryo-electron tomography (cryo-ET) has revolutionized structural biology by enabling the observation and characterization of biological samples at a molecular level in their near-native state [1]. This technique provides an unprecedented level of structural detail, but it necessitates thin specimens (typically below 200nm) for effective electron beam penetration. Presently, the prevailing method for achieving such thinning involves Cryogenic Focused Ion Beam (cryo-FIB) milling [2].

During this milling process, it is easy to miss the regions of interest (ROIs). Fluorescence labeling and fluorescence light microscopy (FLM) can improve targeting [3]. However, the conventional use of a stand-alone cryo-FLM invokes extra transfer steps, increasing the risk of ice contamination, devitrification, and mechanical damage [4]. Moreover, the correlation of the two imaging modalities is cumbersome and often inaccurate, leading to the loss of ROI inside the lamella, rendering it useless, reducing the overall efficiency of the whole workflow.

To address these challenges we present the novel combination of the TESCAN AMBER cryo- FIB/SEM with a fully integrated high quality FLM: Delmic's METEOR system [5]. Thanks to the software integration and position of FLM parallel to the FIB, this novel combination allows smooth and accurate 3D correlation of FLM , FIB and SEM data. Furthermore, the integration of the FLM significantly reduces handling and ice contamination. Additionally, a full collision model allows safe control of the microscope ensuring novel users can adapt the technique quickly. The high-end fluorescent light microscope provides excellent resolution and brings background noise to an absolute minimum allowing researchers to image and mill challenging samples.

In this talk we will delve into the practicalities of this accurate, easy-to-learn and high-throughput correlative cryo-FIB workflow. We will show that the workflow can be used for targeted fabrication of cryo-lamellae from thin specimen (on-grid lamella), larger volumes frozen by waffle method , and cryo lift-out from the most challenging samples. Additionally, we will present the latest results showing EM and FLM data of high-pressure frozen C. elegans and plunge frozen U2OS cells. We will also provide an outlook and highlight the potential of plasma FIB milling, enabling analyses of large biopsies, tissues and small organisms are also discussed.

The novel combination of METEOR with TESCAN AMBER cryo-FIB/SEM allows targeted preparation of cryo-TEM specimen from challenging samples, like high-pressure frozen samples and flat U2OS1 cells.

Poster Group 2

Background
The development of fast pixel-based detectors in (scanning) transmission electron microscopy ((S)TEM) has resulted in 4D-STEM becoming almost a standard tool [1]. The computationally simplest analysis of 4D-STEM data is the calculation of the center of mass (COM) of the intensity in the diffraction pattern (the so-called COM or first-moment method) [2]. The COM corresponds to the expectation value of the net momentum transferred to a beam electron during the interaction with the sample. The momentum transfer is caused by a magnetic or electric field [3]. However, it is anything but easy to draw conclusions about an electric field in the sample from a measured COM. In this contribution, we use the example of AlN/GaN as well as of SiGe/Si to demonstrate effects that influence the measured COM and which may lead to artifacts in the measured electric field. A knowledge of these effects is important for a correct interpretation of the COM measurement [4,5]. We focus primarily on two aims: (i) Deriving the difference of polarization induced fields in GaN and AlN and (ii) measuring the relative mean inner crystal potentials (MIPs) using the electric field at the interface between different materials.
Methods
The investigations are performed by multislice simulations and by experimental 4D-STEM. In the experimental case, an FEI/Thermo Fisher Titan 80/300 and a Thermo Fisher Spectra 300 were used.
Results
Figure 1a shows the projected electric field obtained from a simulated COM measurement [4] along a line profile of an unrealistic, non-atomistic supercell in which a layer with the MIP of AlN is embedded in a material with a MIP corresponding to that of GaN. The x-axis shows the line-scan position, the y-axis shows the simulated sample thickness.
Apparently, the beam electrons at both interfaces experience a momentum transfer towards GaN, i.e. towards the material with the higher MIP. This is intuitively understandable, with the interpretation that an electric field exists - due to the (mean inner) potential difference - that deflects the electrons.
If one now considers the complex propagation and interaction of the beam electrons inside the specimen using an atom-based supercell, one gets a completely different picture shown in Figure 1b: the strength with which the beam electrons are deflected at the interface between GaN and AlN is not just higher - it points in the opposite direction. It can be shown that this simulation result agrees with experimental measurements.
In addition to this example, we will also address the influence of sample geometry (inclined surfaces) and examine what effect beam convergence has and how strongly nanobeam-electron diffraction (NBED) is influenced by it.
Conclusion

The interaction of the beam electrons in the STEM with the sample is strongly influenced, for example, by dynamic scattering. Thus, there are also effects on the measured COM of the diffracted intensity in 4D-STEM image series. Caution is therefore advised when interpreting these COM results (e.g. for quantifying electric fields). For complex and especially small-scale structures, comparison with simulations is a must.

IM-03 (2), Plenary, august 28, 2024, 14:00 - 16:00

Background incl. aims

Transmission electron microscopy (TEM) provides sub-angstrom imaging resolution unmatched by alternative modalities, but cumulative radiation damage to soft-matter specimens can pose an obstacle to applying TEM in the life sciences. Electron Single Pixel Imaging (ESPI) is a computational imaging technique with the potential to dramatically reduce the electron dosage needed to produce high-resolution images [1]. The key idea behind ESPI is to carefully imprint patterns onto the illuminating wavefunction and record the dependence of total scattering on pattern choice [2]. Controlling the illumination in this way ensures that every scattering event contributes useful information toward image reconstruction [3]. The outstanding instrumentation challenge when implementing ESPI is to modulate the electron probe. Here we report a novel, versatile method for imprinting arbitrary patterns onto the electron wavefunction that allows new patterns to be selected several times per second. We show proof-of-principle experimental results demonstrating image reconstruction of a MAX-phase nanoparticle.

Methods

Our modified JEOL TEM, shown in Fig. 1. is operated in pulsed mode: we drive electron emission via femtosecond laser pulses at repetition rates up to 600 kHz. Our column includes a secondary sample holder with a view port located directly below the acceleration section and above the primary specimen holder. In this secondary location, an electron-transparent, optically reflective metal film intercepts both the probe electron pulse and a control laser pulse, mediating an interaction between probe electrons and optical near fields. A Spatial Light Modulator (SLM) imprints a pattern onto the control laser, and the near fields at the metallic film transfer the SLM pattern to the electron beam. The patterned electron beam then scatters off the principal specimen, and diffraction-mode electron optics at long camera length enable detection of the total scattering of the modulated beam.

Results

Figure 2.a. shows a specimen of Ti3Al0.4Sn0.6C2 imaged with conventional TEM. Figure 2.b. shows a representative set of near-field modulated probe illumination patterns, while Fig. 2.c. shows the result of the image reconstruction algorithm applied to this basis set of patterns.

Conclusion

We are actively developing the ESPI technique, in particular, improving the coupling efficiency between control laser and electron probe pulses to provide sensitivity on the level of single-photon exchange. Simulation results suggest that by placing the specimen in the fourier plane of the electron-laser interaction point, we can achieve beam patterning with nanometer feature sizes given a sufficiently coherent probe. We anticipate performing experiments on Li-based electrochemical samples and biologically embedded gold nanoparticles to demonstrate this capability.

This work is part of the SMART-electron Project that has received funding from the European Union's Horizon 2020 Research and Innovation Programme under Grant Agreement No. 964591.

IM-07, Lecture Theater 2, august 26, 2024, 10:30 - 12:30

Background incl. aims
Operando liquid phase electron microscopy (LP-EM) has revolutionized the insights in chemical reactions. Yet, electron irradiation of liquid phases always comes at the cost of radiolysis. Recent advances in simulation allow to estimate the chemical environment and show that the results are drastically altered for different, diluted aqueous systems[1]. With the new generation of liquid cells however, active flow is feasible experimentally to allow a dynamic exchange of the solution.[2] This demands to systematically access these effects. Recently, flow simulations on irradiation of pure water indicate that the flow reduces the local concentration of some, especially long-lived species. Their lack in turn increases the concentration of short-lived reactive species within the irradiated volume.[3] However, experimental validation is pending - a prerequisite to a mature application of LP-EM to more applied systems.

Recent attention has been drawn to silver nanoparticles for CO2 upconversion. To facilitate such studies in in LP-EM, the radiation chemistry of such systems must be well understood. While the radiation chemistry of AgNO3 was estimated in TEM, STEM, and under heatin[4] , the impact of direct flow on beam-induced Ag nanoparticle evolution remains an unknown parameter.

Methods
To overcome this knowledge gap, we provide systematic experiments using a DENSsolutions Stream system and a Thermo Fisher Scientific Talos F200i at 200 kV in STEM mode operated with a beam current of 22 pA. By using AgNO3 as probe solution, we systematically vary flow velocity and dwell time to characterize growth and etching kinetics.

Results
Our findings show that radiolytically-grown Ag nanoparticle behavior ranges from fast growth to dissolution, suggesting a change between reductive and oxidative regime. This is achieved by a change of either flow rate or dwell time, which allowed to empirically map the parameter space. Preliminary results are shown in Figure 1: Growth rate analysis of silver particles (colorbar) for varying dwell times of the scanning electron beam (y-axis) and flow rates(x-axis).

Supporting to the experimental analysis we provide further advances to the automated radiation chemistry tool AuRaCh[5] including interrupted (scanning) irradiation and flow. These findings will provide further insight into the chemistry observed in flowed liquid-phase experiments.

Poster Group 1

Background incl. aims
Transmission electron microscopy is a versatile and indispensable technique when investigating catalysts. When studying metal containing materials, it is of utmost importance to treat the samples under inert conditions in order to preserve the status of air-sensitive samples and their oxidation states as they get easily destroyed or transformed upon contact with air. Usually this is performed using vacuum-transfer sample holders. However, using such holders poses limitations to the investigations that can be performed (e.g., limited tilting range, shadowing effects, etc.). We therefore developed a unique system that allows for the use of all available sample holders without limitations under inert conditions.

Methods
Our novel setup consists of a glovebox system that is directly connected to the TEM. The interface is designed such that it can keep the inert atmosphere while operating and transferring the sample from the glovebox to the TEM. At the same time its construction avoids the transfer of vibrations to the TEM while investigating the sample. The experimental workflow includes the final preparation steps of the sample into the sample holder being performed in the glovebox after inert transfer of the catalyst material to the box. The sample holder is subsequently transferred to the TEM. For high-resolution (S)TEM investigations the glovebox is put in a special operating mode which includes reduced circulation and shutdown of the vacuum pump.

Results
In order to test the specifications of the system we measured the HR-TEM information limit and STEM resolution after connecting the glovebox and compared the results with the tests performed prior to the modifications. The unique modified system is able to operate within the same specifications as the non-modified TEM, in our case even exceeding the specification limits of the vendor. To test whether the samples can be handled under inert condition from inserting to the sample-holder until insertion to the TEM, we investigated two showcase materials. A reduced Cu-metal based catalyst [1] was transferred via the glovebox-system to the TEM and kept under inert conditions at all times. Additionally, a commercially available metallic Cu sample was investigated without inert treatment. Figure 1 a) and b) show an EELS map and extracted energy-loss spectra from the inertly treated sample. It can be seen that the Cu metal is present in its reduced form in the bulk and on the surface. For comparison, figure 1 c) and d) show the same experiments performed on the sample which was not treated under inert conditions exhibiting surface oxidation which can be seen from the Cu_2O spectrum in figure 1 d).

Conclusion
As it is of utmost importance to investigate metal-containing catalyst materials under inert conditions, we designed a modified TEM-system with a glovebox directly attached. We showed that the system is able to function within specifications of the non-modified TEM and allows the investigation of sample while keeping them under inert atmosphere during preparation and insertion to the TEM. This modified glovebox-TEM is currently successfully employed for investigations of different air sensitive catalyst materials as it allows us to use all available sample holders and perform the investigations without the limitations of a vacuum-transfer sample holder.

Figure 1: a) EELS map of a reduced Cu based catalyst [1] investigated in the described glovebox-TEM under inert conditions. b) Extracted EEL spectra from the regions marked in a). The presence of only metal Cu on the surface and in the bulk of the investigated nanoparticle is visible by inspection of the Cu-$L_{2,3}$ edge. c) EELS map of a metallic Cu sample without inert treatment. d) Extracted EEL spectra of the Cu-$L_{2,3}$ edge from the regions marked in c). The presence of Cu_2O in the surface region is clear from inspection of the spectra.

Poster Group 2

Background
The colossal challenge against climate change highlights the necessity of scaling up renewable energy storage capacity and enhancing green hydrogen production by electrocatalysis. However, developing stable and high-performance electrocatalysts for hydrogen production using abundant materials requires a further fundamental atomic-scale understanding of the charge transfer process at the catalytic interfaces.
Although the metal-water interface is the preeminent part of interest for a basic understanding of electrocatalysis and has become an extensively discussed topic in current catalysis research, the atomic structure of the electrolyte, the active sites of the reactions, and the role of single atoms and step edges on the catalyst surfaces remain elusive.
Environmental TEM research enables atomic-scale assessments of metal-water interfaces. We present an open-cell in-situ study of the interface between catalytically active platinum (111) and water vapor under experimentally feasible pressures. Under a water ambient condition, we measure the projected potential across the interface using the angstrom-resolution electron holography method. The results obtained at various external bias conditions are compared to the atomic structures from ab initio molecular dynamics (AIMD) simulations. We will discuss the metal-water interface structures and their natures from experiment and theory.
Methods
A two-electrode MEMS setup is exposed to 50 microbar water vapor, which forms an ultrathin condensed water layer at the Pt electrode surfaces. An in situ analysis is carried out by employing an image-aberration-corrected Titan environmental TEM. Off-axis phase-shifting electron holography is used in conjunction with an improved drift-correction scheme to reconstruct the exit-wave with a spatial resolution up to the information limit of the microscope (<1.0 Å).
Results
The in-situ HRTEM image series and phase reconstructions identify dynamic platinum adatoms at the metal-water interface. The adatoms are residues of the metal-water interface formation and appear only after the electrode is exposed to the water. The existence of the adatoms may depend on the preparation procedures of the metal electrode. By comparing the quantitative frozen-lattice multi-slice simulations, we retrieve the specimen thickness at the edge and, subsequently, the coverage of the dynamic platinum adatoms. At the metal-water interface, the oscillations of the projected potential up to 5 Å above the platinum adatoms are monitored. We interpret the oscillations as preferential orientations of the water molecules in the first water layer with the help of predicted holography data from multi-slice simulations using the AIMD trajectories of the model interface

configurations. Furthermore, we provide an outlook on the influence of external bias on the potential profiles and expectations based on AIMD-simulation for different surface conditions.
Conclusions
In conclusion, we identify the dynamic platinum adatoms at the platinum- (111) interface to water in an open cell ETEM experiment under in-situ conditions. Applying the angstrom resolution phase shifting off-axis electron holography captures the signatures in the projected potential of the first water layers. Based on the multi-slice simulations derived from AIMD trajectories, we attribute these signatures as the preferential ordering of the interfacial water. First experimental indications of the influence of external an bias on the water layer are discussed with respect to AIMD predictions.

Background incl. aims

The MAPKs (mitogen-activated protein kinases) are a family of intracellular protein kinases that form signalling cascades, responding to a number of stimuli, that control fundamental mechanisms such as proliferation, differentiation, inflammation and cell death. The MAPK signalling cascade is highly complex, involving multiple signals (infection, cell stress) and hundreds of interacting protein kinases. In order to tightly control this signalling, the interaction between both activating MAPKs, and deactivating phosphatases, is mediated through recruitment via a binding site between the proteins, distal from the active site, called the D-motif. We are interested in studying the MKK6/p38α MAP2K/MAPK pair as it is a crucial step in a cell's inflammatory and innate immune responses. Both kinases have also been the subject of intense study by the pharmaceutical industry, with several compounds targeting p38α in phase II clinical trials [1]. The interaction between p38α and MKK6 is transient and the timing and location of each component during stress is unknown at high resolution. We have generated HEK 293T cell lines expressing MKK6 and p38α, respectively harbouring europium and nickel binding tags. Using XRF microscopy we seek to trace the cellular movement of the two partners in the cytoplasm and nucleus during steady state conditions and under cellular stress. Crucially, the possibility of differential labelling will be demonstrated, allowing us not only to track the proteins in the cell at high resolution but also to see when and where they co-locate. We have recently determined the cryo-EM structure of the MKK6/p38α transient complex [2] (Fig.1) and complementing molecular details with cellular spatio-temporal insights will further help deciphering the inflammatory response.

Methods

This project involves the use of a HEK 293T derived cell line expressing tagged MKK6 and p38. Such cell lines will be targeted in the same experiment for both Ni2+ (p38α tag) and Eu3+ (MKK6 tag).
1. HEK 293T modified cell line will be cultured in complete medium (DMEM+10% FBS) supplemented with 500 ug/ml geneticin & 4 ug/ml puromycin. HEK cells (WT) will be cultured in complete medium.
2. 24h before the Ni/Eu treatment, the double tagged cell lines will be treated with doxocyclin (1ug/mL) inducing expression of tagged p38 and MKK6.
3. HEK 293T modified & WT 293T will be seeded on Si3N4 membrane (Silson, UK) (20000 cells/membrane) [3].
4. Cells will be treated with Ni2+ and Eu3+ (250 uM each) for 24h. A negative control will be performed with HEK WT cells without any Ni/Eu treatment. (concentrations defined based on cytotoxicity assay analyses).
5. After treatment, cells will be washed and subcellular organelles will be labelled with fluorescent markers for 30 min.
6. The cell samples will then be cryofixed in LN2-chilled ethane with Easygrid [4] and stored in LN2 prior to analysis at ID16A.
7. Samples will be placed into the cryo-stage at ID16A for analysis by cryo-correlative X-ray fluorescence microscopy and phase contrast imaging.

Results & Conclusion
We already obtained the cryo-EM structure of the MKK6-p38α complex during activation showing how the MAPK is bound and activated by its MAP2K (Fig.1). However, we would like to go a step further and study the MKK6/p38α transient complex [2] in cellulo and complementing molecular details with cellular spatio-temporal insights will further help deciphering the inflammatory response. Tagging each protein with a different metal atom, we will then be able to select the region of interest showing where and when the two proteins interact. An optimal sample preparation is then required and using the EasyGrid platform [4] which is an automated cryo-EM grid preparation and control system enables high reproducibility and improved in-depth vitrification of cells (compared to traditional plunge-freezing techniques), we might obtain ideal conditions to perform the full study. In order to define the cell regions before XRF, we will use fluorescent markers to identify the location of organelles in order to relate them to the distribution of the tagged proteins. This will also help to preselect the region of interest of our samples before XRF studies. Our expectations that the double tag might be validated very soon with synchrotron X-ray fluorescence nanoimaging beamtime on the ESRF ID16A beamline. Even if the concentration of the Ni/Eu that will be bound to the cells are extremely low, thanks to the high synchrotron flux we are waiting to see a colocalization of Ni-Eu signal at locations within the cells. Obtaining this information on the inflammatory response will be a crucial to decipher and understand the inflammation chain reaction involved in diseases and could lead to the onset of new therapies.

Poster Group 2

Short-period superlattices comprising ultra-thin InGaN/GaN quantum wells (QWs) with thicknesses of a few (0002) monolayers (MLs) have attracted considerable interest within the field of advanced optoelectronics. These nano-heterostructures offer the potential to manipulate the bandgap through precise control over both the QW and GaN barrier thicknesses [1]. Furthermore, their potential applications in quantum computing and spintronics have been spurred by the possibility of topological insulator behavior [2]. These crucial properties are intricately linked to the indium content within the QWs. Growth efforts strive to achieve high-quality heterostructures with high indium content and QW thickness of less than 5 MLs. This study aimed to determine the impact of growth temperature on indium incorporation and minimum QW thickness down to a single ML, by employing a methodological approach utilizing quantitative analysis of probe-corrected HRSTEM observations.

Methods

Multi-quantum-well (MQW) samples were grown by plasma-assisted molecular beam epitaxy under highly indium-rich conditions. These conditions included In:N flux ratios of 3:1 or 6:1 and InN growth rates of 0.25 or 0.15 ML/s. The objective was to kinetically stabilize QWs with nominal thicknesses of only 1 or 2 MLs. The MQWs were fabricated with either 3 or 5 periods. The thickness of the GaN barriers was maintained at 10 nm. Both the QW and GaN barrier growth temperatures were systematically varied. An integrated characterization approach was implemented to comprehensively analyze these nano-heterostructures. This approach encompassed quantitative analysis of probe-corrected HAADF HRSTEM observations. A peak finding algorithm utilizing 2D Gaussians was implemented to determine the atomic column positions within the experimental HRSTEM images with sub-Angstrom precision. These positions were subsequently used for nanoscale strain mapping and measurement of the atomic column intensities via a 2D Voronoi tessellation applied to each image. For Z-contrast quantification of the atomic column intensities, comparison to frozen-phonon HRSTEM image simulations was employed. The latter were generated from supercells relaxed using either density functional theory or empirical potential calculations with a modified embedded atom method interatomic potential [3-5].

Results

HAADF HRSTEM observations along the <11-20> zone axis of the wurtzite structure were employed for quantitative Z-contrast and strain analysis. Empirical potential calculations were conducted to determine the strain behavior of QWs with thicknesses of 1 and 2 MLs. A significant number of InxGa1-xN/GaN QW supercells spanning the entire compositional range, including both ordered and random alloy configurations, were constructed, and relaxed under biaxial strain conditions. These

calculations yielded composition-dependent strain profiles. Subsequently, the relaxed supercells served as input for the multislice HRSTEM image simulations. Consequently, graphs of InxGa1-xN/GaN column intensity ratios versus TEM foil thickness were generated, facilitating the correlation between QW composition and average column intensity. The analysis explicitly considered the effects of thin foil relaxation, the presence of amorphous surface layers and the cross-scattering phenomenon. The latter was identified as leading to an artificial intensity enhancement of the adjacent GaN MLs of the QWs, particularly at large foil thicknesses. The HAADF HRSTEM observations were then compared to the strain and intensity calculations in order to determine the indium contents within the QW MLs. The evaluation of the results allowed the elucidation of the crucial role of growth temperature in governing the indium incorporation and the QW thickness. A synthesis model explaining the nanoscale processes occurring during epitaxial growth was subsequently proposed.

Conclusion

This work emphasized the importance of an HRSTEM-based methodology for determining the composition of ultra-thin InGaN/GaN QWs. The indium content was determined directly through quantification of Z-contrast and indirectly through measurements of lattice strain. Quantification of Z-contrast utilized thickness-composition-intensity ratio maps obtained from image simulations. Similarly, lattice strain measurements were translated to indium composition by employing the theoretically derived strain-composition coupling of such thin nano-heterostructures. The development and application of this integrated approach were necessitated by the requirement for sub-nanometer accuracy in compositional and strain analysis of low-dimensional materials. This accuracy is crucial for defining their structure-composition-properties relationship.

Poster Group 2

Classical nucleation theory (CNT) is used to describe the growth of metal nanoparticles by seed formation from insoluble metal atoms generated by chemical reduction of precursors containing metal ions. It involves a nucleation step, and subsequent monomer attachment on the seeds which is limited by diffusion of metal atoms.

In contrast, liquid phase transmission electron microscopy (LPTEM) has revealed that nanoparticles do not form by the above-mentioned process but via cluster-cluster aggregation instead.[1] Although this non-classical growth of nanoparticles has been observed frequently, precise knowledge about atomic and cluster species remains concealed. Mechanisms comprising thermodynamically preferred cluster sizes have been suggested in prior studies. However, these magic clusters cannot explain formation mechanisms involving strong reductants at room temperature where kinetics are dominated by the reaction.

In LPTEM, reaction kinetic modeling has been shown to facilitate uncovering reaction conditions in irradiated solutions and how to tailor redox chemistry [2] and acidity [3] in precursor solutions with radiation.

Unraveling ionic precursor species guiding the formation pathways of metallic nanoparticles would enable to specifically design synthesis routes and thus to deliberately adjust their nanostructure properties.

Herein we correlate liquid phase electron microscopy with reaction throughput analysis to demonstrate that nucleation and growth of silver nanoparticles is based on aggregation and attachment of various metal clusters and ions. Therefore, we utilize LPTEM to study nucleation and growth rate of silver nanoparticles induced by radiolysis of aqueous silver nitrate solution. [4] Observations are complemented by a time dependent radiolysis model of the precursor solution (Figure 1a and 1b) illustrating the concentration of most silver species being directly proportional to electron dose rate (Figure 1c).

LPTEM measurements revealed a nearly invariant nanoparticle growth rate with increasing electron dose rate and a decreasing nucleation rate (Figure 1d and 1e). Furthermore, our reaction kinetic model suggests that Ag_4 and Ag- have steady state concentrations orders of magnitude larger than those of the other species which are also almost invariant with dose rate. Experimental dose rate dependent growth and nucleation rates were fitted by power laws yielding growth exponents of $(2.5 \pm 7.5) \cdot 10^{-2}$ and -0.17 ± 0.07, respectively (Figure 1d and e, red lines). The large concentrations of Ag_4

and Ag- in combination with their dose rate dependent power law exponents of $(-7.5 \pm 1.0) \cdot 10^{-3}$ and $(6.5 \pm 2.6) \cdot 10^{-3}$ indicated by our kinetic model and located within the error margin of the experimentally obtained data, suggest a nanoparticle growth by attachment of Ag_4 and Ag- to the silver seeds. However, the nucleation rate exponent did not match any of the simulation results. Furthermore, CNT evaluation yields very high supersaturation values suggesting unrealistically small critical radii of no more than a single atom.

The inconsistency of the dose rate dependency of the observed nucleation rate with that of all silver species and CNT suggests a silver nanoparticle growth via a non-classical pathway. Our results provide evidence, that nucleation rather takes place in a millisecond time scale which is dominated by Ag_4^{2+} cluster-cluster aggregation. Overall, this work showcases the power of quantitative LPTEM combined with transient reaction kinetic modeling for disentangling which chemical processes are involved in nanoparticle formation.

Poster Group 2

Background incl. aims
While dynamical scattering has typically been viewed as a hindrance when attempting to retrieve an unknown crystal structure from electron diffraction data, it can also be of direct benefit since it encodes phase information in the intensity of the electron wave function exiting the crystal [1]. For example, recent advances in 3D electron diffraction have utilized dynamical effects to complement and significantly improve kinematical refinement methods [2]. Building on prior work by Feng et al. [3] we have developed a structure retrieval method which, using experimental large-angle-rocking-beam electron diffraction (LARBED) data, is not only capable of reconstructing complex crystal structures, but also shows that dynamical scattering can be directly used to increase the resolution of a reconstruction beyond what would be achievable under assumption of purely kinematical conditions.

Methods
The approach by Feng et al. [3], which was demonstrated on a rather simple structure (SrTiO3), used a conjugate gradient method to minimize the sum of squared differences between an experimental LARBED pattern and one simulated via the Bloch wave formalism from reconstructed structure factors. We expanded on this method by switching to the adaptive moment estimation (ADAM) optimization algorithm as well as introducing analytical calculation of gradients of the scattering matrix. Significant improvements were achieved by utilizing a series expansion of the scattering matrix [4] to develop a weighting scheme which selectively prioritizes matching those diffraction intensities which have a dominating linear dependence on the structure factors of the crystal. Experimental measurements were performed using a Dectris ELA detector mounted to the end of the IRIS spectrometer of a Nion HERMES microscope, allowing zero-loss filtering with the energy-selecting EELS beam trap. The results presented below were achieved using a roughly 40nm thick lamella of β-Ga2O3 which was prepared with the FIB technique from a bulk crystal grown by the Czochralski method [5].

Results
Figure a) shows the 2D projected potential of β-Ga2O3 in [010] zone axis, generated from reconstructed structure factors, with the theoretical structure overlaid on top. The structure factors were refined from 1129 diffraction patterns of an experimental LARBED tilt series, collected with an accelerating voltage of 200 kV and a maximum tilt angle of 100 mrad. Figure b) shows the Fourier transform of the reconstructed potential with the red circle indicating the range of visible frequency components (image is not to scale with a)). Figure c) shows the mean of all experimental diffraction patterns collected in the LARBED measurement. While many excited beams are visible, only the first 8 (indicated by green circles) were actually used in the reconstruction of the crystal structure. Our

method reaches a sub-angstrom resolution of 1.39 Å-1, which is over 5 times finer than the maximum resolution of 0.27 Å-1 which one obtains when only using the structure factors corresponding to these 8 beams, as in kinematic scattering theory. The reconstructed potential shows good agreement with reference data, further validating this result. In addition to the crystal structure, a specimen thickness of 36.9 nm was also retrieved. The reconstruction was performed ab-initio, i.e. without initializing it with any reasonable starting guess. Besides a small regularization term in the loss function to aid convergence, no further constraints were placed on reconstructed structure factors and no prior information about the crystal, except for its lattice parameters (which can also be extracted from the diffraction data), were used.

Conclusion
In summary, we have directly utilized experimental dynamical diffraction data to perform an ab-initio reconstruction of a crystal at a much higher resolution than would be possible with purely kinematical methods. While we show the best result in this text, our method has successfully been tested on experimental data from further crystals, such as BaTiO3 and Al2O3. An interesting consequence of these findings is that it may be possible to reconstruct a 3D structure from 2D rocking curve data, since there is no fundamental difference in how structure factors corresponding to different reciprocal lattice vectors influence the diffraction pattern produced by the crystal. Preliminary testing on simulated data appears to be promising in this regard and will be further discussed.

Poster Group 1

In four-dimensional scanning transmission electron microscopy (4D STEM) imaging, a focused beam of electrons scans the sample in a two-dimensional (2D) raster pattern, while a two-dimensional (2D) image is recorded at each scan position. This technique is meanwhile commonly used and is applied to a wide range of materials. We present an ultrafast and direct electron detection system, the pnCCD (S)TEM camera which is equipped with a novel chip with a center hole in the middle of the detector. The annular pnCCD sensor with a central hole (264x264, 48µm2, physical hole 2.5mm diameter) allows the central beam component to pass through the detector, thus becoming available to the EELS instrumentation, without losing the possibility to reconstruct 4D data. The pnCCD (S)TEM camera is compatible with electron energies ranging from 10 keV to 300 keV and can be operated with up to 7500 frames per second. If long dwell times are used for the EELS measurement, online averaging over any number of frames is possible to reduce data while extending the dynamic range by reading out multiple times per scan pixel.

The simultaneous acquisition of electron energy loss spectroscopy (EELS) data and diffraction signal using two hardware synchronized instruments adds attractive information about the sample like elemental composition, phonon or plasmon excitation or core loss phenomena. With formerly available detector systems, a decision needed to be made if either a 4D STEM or an EELS measurement is taken.

In this contribution, we show details of the new sensor and first measurement results recorded at 200keV on a JEM-F200 (JEOL Ltd.) with a cold field emission gun using a prototype camera. The data show that the experimental conditions for EELS and 4DSTEM can be matched and, most importantly, no disturbance in the EELS data is found due to that fact that the electron beam passes through the pnCCD detector.

Background incl. aims
Texture describes the preferred orientation of grains in crystalline materials, which dictates their anisotropic, for example, (opto-)electronic, thermal transport, and mechanical properties. The texture is evaluated conventionally by probing the reciprocal space using X-ray and/or electron diffraction methods, where spatial information, e.g., the orientation relationship of particular grains, is hardly accessible. Probing the local diffraction pattern with a focused electron beam, i.e., nano-beam diffraction (NBD) 4D-STEM, provides local structure information. Recent detector technology opened new possibilities to perform such experiments at ever-higher temporal resolution.
In this contribution, we discuss the optimized conditions towards in-situ 4D-STEM observations of texture evolution in thin films by a combination of state-of-the-art fast direct electron detector (DED), dose-efficient experimental approach, and novel algorithms of data analysis.
Materials and methods
Two material systems, (I) a beam robust poly-crystalline gold thin film and (II) an extremely radiation-sensitive bulk hetero-junction (BHJ) blend used as active layers in organic solar cells serve as model samples in this study.
For poly-crystalline gold, we deposited 15 nm gold with PVD on the SiNx windows of MEMS heating chips (DENSsolutions Wildfire) and annealed the film in the TEM at 150^{o}C for 180 s while observing coarsening of the nano-crystalline structure. 4D-STEM experiments were carried out using a Thermo Fisher Scientific Spectra 200 TEM operated at 200 kV in a regular nano-beam diffraction setup and data was acquired using a DECTRIS ARINA detector. The orientation maps are then analyzed using the ACOM [1] routine within the py4DSTEM package and custom codes to streamline the output orientation matrix to the Orix package [2] for further evaluation of the texture evolution.
The BHJ thin film of nominal thickness of 80 nm comprises small molecule donor DRCN5T blended in fullerene acceptor PC71BM as reported earlier [3,4]. The major challenge is the dose budget (< 5 e-/Å2 at room temperature) that limits the applicable probe current for structural elucidation.
Results and discussions
For gold nano-crystal thin film (Fig. 1a), despite being radiation robust, it remains very challenging to observe evolution at high spatial and temporal resolution with sufficient angular resolution and sampling in diffraction space for orientation determination. This is due to the high dimensions of data required and the limited dose rate at the single pixel level of DED detection. To overcome this limit, we realized that an appropriate convergence angle and camera length are the key factors (using a standard NBD setup) that control the reciprocal space coverage and sampling. It is important to balance DED saturation in the primary beam and sufficient SNR of weak Bragg disks for accurate disk detection and subsequent crystal orientation matching. With a larger convergence angle, a higher probe current at a given high speed of detector readout, thus a higher dose, can be applied. While a small convergence angle seems arguably to favor angular resolution for Bragg disks detection, it

lowers the applicable probe current due to detector saturation, resulting in weaker Bragg disks fading in the diffuse scattering background. After optimizing conditions on our experimental platform, we found that time resolution of 5 – 10s and sub-3 nm sampling resolution (probe size <1 nm) for a statistically relevant field of view is realizable.
We further discuss strategies to improve the dose-effectiveness in terms of Bragg peak detection and eventually, in-situ 4D-STEM experiments supported by experimental results. These include (I) elastic energy filtering, (II) amplitude grating using patterned probe-defining aperture [1], and (III) applying precession-assisted 4D-STEM [5].
Finally, we were able to visualize the grain orientation from optimized, standard NBD 4D-STEM datasets and track the evolution of texture evolution of a defined ROI from the early stage on. We observed the growth of <111> oriented grains at the cost of neighboring high-index oriented grains (Fig. 1a). The 4D-STEM datasets allow grain orientation relationships to be analyzed qualitatively as well as quantitatively, shedding light on the complex interplay between various factors including types of grain boundaries, defects, and even local strain.
In the case of extremely dose-budget limited scenarios like the molecular nano-crystallites in the BHJ, the ultimate Bragg peak detectability is limited by the Poisson noise of the scattered electrons that strike on detector pixels. Therefore, the focused electron diffraction pattern is advantageous.
Inspired by earlier work of ultra-high angular resolution ω-q mapping [P. Midgley, Ultramicroscopy 76(1999) 91], we established a dose-efficient approach, 4D-scanning confocal electron diffraction (4D-SCED), to study the texture structure, i.e., face-on and edge-on domains, of nano-crystallites of the donor in the BHJ (Fig. 1b). 4D-SCED applies defocused pencil beam illumination on the sample and combines a confocal electron optic setup with a pixelated detector to record focused spot-like diffraction patterns. The defocused illumination reduces the dose and generates a homogenous beam-specimen interaction. At the same time, the confocal optics generates spot-like diffraction signals, boosting both the signal-to-noise ratio and signal-to-background ratio even in Poisson noise-limited scenarios [4]. We demonstrated a quasi-in-situ observation of the molecular nanocrystallites' structural evolution during an annealing experiment using a CMOS detector [3] (Fig. 1b). We further discussed new avenues to further reduce dose, improve experimental speed (temporal resolution) and throughput using a fast hybrid pixel detector, and advantage of the frame-based detector over the current generation of event-based detector for these applications [4].
Conclusion
In the study of nano-crystalline structural evolution, the achievable temporal resolution of in-situ 4D-STEM experiments is dose-limited at detection saturation level, independent of sample radiation resistance. Besides calling for further improvements of detectors, we present and discuss several experimental strategies for both beam robust and beam sensitive samples to optimize conditions to spare the meaningful dose to Bragg signal detectability and structural determination.

Poster Group 1

In the TEM community, four-dimensional scanning transmission electron microscopy (4D STEM) imaging is meanwhile a commonly used technique for a wide range of materials. In a scanning electron microscope (SEM), usually the backscattered and emitted electrons from the sample surface are recorded by the available detectors. The used electron energy is typically at 30keV or lower. If a thin sample is to be measured in transmission, single cell or multi-channel STEM diodes are used to collect STEM images at a fixed distance below the sample, as there is no optical lens between the sample and the detector. This allows for basic bright field (BF) or differential phase contrast (DPC) signatures to be measured.

To open the use of SEM instrumentation to a broader range of applications and more complex investigations, we used our pixelated pnCCD (S)TEM camera [1] with 264x264 pixels to perform first 4D STEM measurements in a SEM. The camera can record up to 7500 frames per second, which corresponds to a dwell time of 133 microseconds. We modified the camera design such that a compact detector module is placed below the sample position along the optical axis of the microscope, while the camera electronics is mounted outside the vacuum chamber.

In this contribution, we present first measurements with the pnCCD (S)TEM camera operated at room temperature (see Fig. 1) in a Tescan Mira3 SEM, taken at different electron energies from 9keV to 30keV.

Identification of inorganic fibres in workplace air by SEM-EDS

Dr. Markus Mattenklott[1], Dennis Kaiser[1], Bianca Gasse[1]
[1]Institute for Occupational Safety and Health (IFA), Sankt Augustin, Deutschland

Poster Group 2

When assessing fibre dusts in the air at workplaces, it is crucial to identify and classify the type of fibre in order to distinguish carcinogenic fibres from others from an occupational health and safety perspective. Up to now, this has been done using an error-prone method of product fibre identification. The aim of the project is to create a database for determining the type of fibre independently of reference materials from the sampled work areas and, based on this, to define identification criteria.
Using available reference materials from the synthetic inorganic fibres used in work areas (synthetic mineral fibres, high temperature wool, micro glass fibres, textile glass fibres, etc.), the range of element composition of the fibre types is determined by means of EDS analysis. In addition, systematic investigations are used to determine the quality of these analyses of fibres with diameters in the micrometre range, identify systematic problems and derive possible differentiation criteria. This database is supplemented by information from publications and manufacturer data, which have been structured for comparison with EDS analyses
A scheme was established that allows fibres in airborne dusts to be classified largely independently of reference materials. It is important not only to look at individual particles separately, but also to classify the fibres found on the basis of previous grouping.
The presented solution to the problem of identifying fibres shows the limits of manual classification. A further step will be the establishment of self-learning neural networks, which have already achieved successful results in initial tests in this area and provide constructive support for identification.

Automated feedback correction of the specimen drift at the atomic scale

Dr Christophe Gatel[1]
[1]CEMES-CNRS, University Toulouse III - Paul Sabatier, Toulouse, France, [2]CEMES-CNRS, Toulouse, France

IM-02, Lecture Theater 3, august 27, 2024, 14:00 - 16:00

Background
Transmission electron microscopy (TEM) has always been an active subject of research, in particular with the advent of new instrumentation like brighter electrons sources, sensitive cameras (direct electron detection), phase plate and vortex beam, aberration corrector, high collection angle EDX detector. Such new advanced capabilities have improved conventional TEM techniques to higher resolution (spatial and in energy) and better signal–to-noise ratios (SNR).
In parallel to these instrumental and methodological developments, automation of the electron microscope has become an essential tool in cryo-microscopy for recording images of many specimen areas and defocus values for single-particle analysis [1], or in the acquisition of tomographic tilt series, diffraction tomography, and holographic tomography [2]. Further refinements include object displacement and focus prediction to accelerate acquisition of tilt series for shorter acquisition and less beam induced damage, online reconstruction of tilt series for preliminary inspection of data at the microscope, alignment of individual particles in images to correct for beam-induced movement. More recently, automation has been developed for 4D-STEM data acquisition, and pipeline acquisition and analysis for routine sample studies.
In these examples of automation, the specific sequence of images is recorded with predetermined experimental conditions. High numbers of images can thus be easily acquired without requiring any operator interaction, leaving human errors and fatigue out of the acquisition process. The computer-controlled execution can thus reduce the time the specimen is exposed to electrons and improves the studies of beam-sensitive materials. In addition, series of images acquired on the same area with a short exposure time to minimize the effect of instabilities, mainly the specimen drift, can be realigned using sophisticated post-processing and summing to improve the SNR. However, the latter approach generates large volumes of data, requires significant calculation time and reduces the field of view of the final image by keeping only the common area of all the images making up the series. The field of view is all the more reduced if the drift is significant. It is therefore interesting to consider whether the specimen drift could be carried out continually and autonomously during image acquisition, or experiments in general, and to investigate the precision with which dynamic drift correction can be achieved [3].

Methods
For several years now, we have been developing software tools to dynamically stabilize experiments. The position of the region-of-interest is determined continuously by analyzing the live flow of images from the camera coupled with feedback control to the specimen stage, or image deflection coils, to stabilize the position mechanically or optically, respectively [4]. This plugin can be installed on any platform (microscope + computer) equipped Digital Micrograph and any type of STEM camera or detector.
The specimen drift measured between two successive images can be corrected on a time scale of less than a second by the use of speed-optimized routines. Whilst the image deflector coils can be used

for optical correction, we have mainly worked on mechanical stabilization of the stage in order to preserve the optical alignment and to maintain identical conditions during observations.

Results
We tested our approach on several different microscopes from different manufacturers. In addition, different modes of observation (Lorentz mode, high-resolution TEM or STEM) have been used, combined with in-situ experiments (biasing, temperature). We will show that stabilization at the atomic scale can be obtained for an unlimited time if the stage is equipped with piezoelectric movement.

The figure shows HAADF high-resolution STEM images acquired on a BaTiO3 thin film epitaxially grown on a SrTiO3 substrate. On the left are presented an image recorded in normal conditions during 30 s with the corresponding phase image extracted using the geometrical phase: scan error and distortions are clearly visible. On the right the same images recorded during 60 s using automated feedback of the piezostage allowing accurate correction at the atomic scale.
We will thus discuss the precision of the correction and the perspectives for HR-STEM studies for which scan errors and distortions are eliminated, or for studies of change at the atomic scale as a function of temperature.

[1]University of Illinois at Urbana Champaign, Urbana, United States, [2]Materials Research Laboratory, Urbana, United States

IM-06 (2), Lecture Theater 1, august 30, 2024, 10:30 - 12:30

Background
Electron crystallography provides a pathway to solve structure of small crystals (< 1um) in size, and thus overcomes difficult synthesis constraints involved in growing large crystals. Generally, electron diffraction data is collected in the form of integrated intensity using continuous rotation or by precession. The measured intensities in 3D are utilized for structure solution. Using this approach, structure solution of difficult crystals, such as small crystals of zeolites, metal-organic frameworks, molecular crystals, and proteins , can be solved by electron diffraction.
However, electron structure solutions are regularly reported with higher R-values than x-ray or neutron diffraction. While similar structures are found despite the high R-values, the differences in the measure intensity and theory calculated intensity limit information that can be extracted by electron diffraction. Previous work demonstrated that including multiple-scattering effects significantly reduce the R-values . Thus, it is critical to be able to quantify the dynamical diffraction effects in molecular crystals.
Aims
Here, we introduce the large-angle rocking beam electron diffraction (LARBED) technique implemented with hardware synchronization for the quantifying dynamical scattering in large unit cell and dose sensitive crystals, such as zeolites. We report LARBED measurement from zeolite-Y crystal. The resulting patterns show the effects of dynamical interactions when scattering through an imperfect crystal. Our aim is to provide an example of the type of interactions which are limiting the statistical accuracy of methods like microED. Furthermore, we suggest that LARBED can be utilized as a complementary method, where solving the LARBED pattern will provide enhanced statistical accuracy.
Methods
The LARBED technique was implemented on an FEI Themis-Z microscope operating in precession mode with a TEM nanobeam diffraction probe. Here we establish a dark field pivot point aligned to the bottom of the sample with the range of the LARBED pattern set as the precession angle, here, 60mrad. This setup allows for a scan generator to drive the scan coils to tilt the beam rather than rastering the beam in real-space as in standard 4D-STEM techniques. The signal then incrementally tilts the beam with a step size corresponding to the precession angle divided by the integer size of supplied signal grid. The signal was provided using the synchronized scan generator of an electron direct detector. This allows for high-throughput data collection, where 128x128 scans are taken in 17seconds providing high resolution rocking beam curves while maintaining a lower dose. Additionally, dose was minimized using the monochromator slit to 2pA and ~ 0.2mrad convergence angle as a 4.5nm FWHM probe. The Zeolite-Y sample was prepared as a dried powder on an ultrathin lacey carbon grid.
Results
Figure 1 shows the LARBED pattern of a 60 mrad [100] obtained from a Zeolite-Y crystal. The collected datasets are a 4-dimensional stack of diffraction patterns of shape. Here, data are individual
